One other thing that must be noted if one wishes to transmit, the power MUST be turned off to the servo motor or the RF will cause it to chatter violently thereby detuning the loop and affecting SWR

I mostly use my loop for receive but it seems to work just fine on transmit. Where it really shines is in eliminating the high level of local static that I often get on the 40 meter band in the mornings and evenings. The loop can knock an S-9 noise level down to a S-3 often rendering a previously unheard signal into a solid copy with 2 S-units over the noise.

Interesting! I never thought to run the wires inside the loop itself!
It doesn't let RF into the shack? I would think the cable would upset
the SWR or you would at least need to isolate it with chokes and
bypass caps.

Is that ABS pipe holding it all up? Nice looking loop, is it
rotatable? What are the dimensions? Thanks for posting,

Pappy Hiram

Dear Garry

can you give us a hint how you are able to change the capacitance
from the shack

nice photos

Paul in Guelph ON

Hi Paul.

I can pass on my method. First things first. I am using a homebuilt
air-variable capacitor that seems easily able to handle the 100 watt
output from my radio. Over time I have learned that making a remote
tuning device to work it is not so simple as one might think. The
first thing I found out was that anything in the plane of the loop
wanted to effect the SWR so I had to devise a method of circumventing
that.

I finally settled on using a servo motor such as I use in my model
airplanes. The requirement for one is not particularly stringent as
the capacitor is very low friction (Butterfly type of capacitor) so
any cheap servo motor seems to do the job. The servo motor is fixed
directly to the capacitor shaft and the three wire cable to provide
the signal is routed through the 3/4" pipe that forms the loop.

Nice

as the other fellow indicated wha happens with this wire set "crosses" the rf current path,
something induced or not??

tDoing this takes it out of the planetf the loop and has no apparent
effect on performance of the loop.

very good

The following numbers are "item numbers" from Ebay auctions:
320309451655, 290266317566

Go to Ebay.ca or Ebay.com and enter the numbers in the search window
and the specific listing will be brought up. (note: these numbers
will only be good for a couple of months then they will expire from

the Ebay system, -- An alternative would be to search for Servo
Tester on Ebay)

These devices are servo testers that RC enthusiasts can use to adjust
the servo motor settings on model cars/aircraft without having to
connect them to a receiver. The less expensive one is rather simple
(and small) but works just fine. The more elaborate one has a
digital readout that displays the pulse width being generated and can
be used as the loop tuning device with complete accuracy.
Repeatability is excellent with this device.

nice adaption

I did find that I had to use a stable regulated power source in the
shack as a DC wall wart did not work when under load as the circuit
became unstable and the servo motor chattered considerably. What I
used (quickest for me) was a battery pack consisting of 6 NIMH
rechargables. I have 75 feet of cable from the shack to the loop.
Other than the fact that the tuning is very touchy, it works
beautifully and I learned very quickly which numbers on the readout
correspond with my most used frequencies.
any way to add a wormgear to further reduce turning ratio

One other thing that must be noted if one wishes to transmit, the
power MUST be turned off to the servo motor or the RF will cause it
to chatter violently thereby detuning the loop and affecting SWR

ok copy that

I mostly use my loop for receive but it seems to work just fine on
transmit. Where it really shines is in eliminating the high level of
local static that I often get on the 40 meter band in the mornings
and evenings. The loop can knock an S-9 noise level down to a S-3
often rendering a previously unheard signal into a solid copy with 2
S-units over the noise.

very well done

thanks

Paul

Pappy,

Yes that is ABS pipe holding it up but there is a planed down 2" x 2" inside of the pipe to add support. The ABS really wants to warp in the strong sun.

I found that running the power/pulse signal wires external to the loop messed up the SWR (badly). By running the wiring inside of the pipe and exiting at the bottom alongside of the coax, I can find no degradation or at any rate minimal degradation of SWR and performance would appear to be unaffected. I do not notice any RF in the shack. I did try to bypass with a couple of caps but ended up removing them with no noticable affect.

Remember that the current on the loop conductor will only be running on the outer skin. I deduced that there would be no effect on the loop if a wire was run internally and it would seem to be the case with this loop.

The loop is rotatable (by hand) however, other then for using it to null out a particularly annoying noise source I have not found any need to rotate it. I have it sitting East/West. This loop is about 62" in diameter (slightly under 2 meters for you metric folk) The loop works 20 meters, 30 and 40 with the present capacitor. The loop design program indicates app 50% efficiency on 40 meters and around 90% effeciency on 20 meters.

I had suggested this some time back, but was largely ignored. Thanks for confirming that this works.

Might I add a little here? I'm a very long time R/C'er.

A servo can be had for less than $10 USD. Even some of the store brand models, such as from Tower Hobbies, are excellent servos and better than what we had years ago.

The servos require 4.8 vdc (4 nicad cells) to 6.0 vdc (4 alkalines) to operate. I don't know what the upper limit is, as I've not had a reason to push them to higher voltages. A servo only requires about 10 ma idling current, and in operation averages about 100 ma. Stalled, it may take about 200 ma.

I have operated them from higher voltage supplies using an LM7805 (5v) or 7806 (6v) chip regulator. If a wall wart is causing the jitters in the servo it is because it is not supplying clean power. Using a higher voltage wall wart, and going through a 7806 with a capacitor on each side (input to ground, and output to ground) for filtering will work just fine.

Since long leads will be used, I would use 6v to power the servo.

There are three leads, black is common or -. Red is +. White (or sometimes another color, but usually white) is signal. The signal consists of a positive pulse in the 1.0-2.0 ms width range. The exact pulse width determines the position of the servo. Most radios

are made to center the servos at 1.5 ms. Futaba centers at 1.37 ms, but there is enough range that it does not matter. The frame rate (how often pulses are sent to the servo) is around 50-60 hz.

At one time I saw a little computer program and adapter from a serial port used to run a servo. Perhaps one of the Radio Shack robotics kits might be used.

Usually the amount of rotation is 90*. Landing gear servos rotate 180* and produce a lot more torque, way more than required for a tuning capacitor. and are very expensive. But a capacitor requires 180* of rotation. If the servo tester does not provide enough range, open the servo and find the feedback potentiometer. This is easy as it is directly below the output shaft, and is rotated by that shaft. The amount of rotation can be increased by adding a 1/8 watt resistor to each of the outer legs of the pot. Try 2.2k to 4.7k. Unsolder the wires (leave the center wire attached), and solder one resistor to each end terminal, solder the leads back to the resistors.

You can connect the servo to the tuning capacitor with a piece of vinyl tubing forced over the output shaft and the capacitor shaft.

The servo can be secured with double sided foam tape.

The resistors can be tucked in beside the feedback pot so they are not in the way and won't short on anything. There is not enough room to use heatshrink tubing.

Yes, the servo has more than enough torque to turn a tuning capacitor.

Paul C.

with the advent of 2.4ghz spread spectrum rc transmitter and receivers it might be feasible to make the tuning wireless. the 2.4ghz receivers are tiny have very small antenna requirements for flight and likely would work with even smaller antennas for this stationary short distance use.

since the receivers and servos work on battery power by design it might even be possible to have the whole tuner assy solar powered. ensuring that the torque necessary is minimal is just a matter of minimizing bearing friction to minimized battery drain.

that would mean that no wiring would be required at all in the plane of the loop or through the loop itself.

even if solar isn't used it should be possible rig the tuning assy up with rechargables suitably housed for easy access.

Good information Paul. Thanks.

The only thing I would mention is that the butterfly capacitor (at least the one that I have) requires only 90 degrees of rotation as opposed to the standard capacitor at 180degrees. The butterfly is the best bet as there are no losses associated with sliding or rotating contacts such as you would have on the other style of capacitor. The capacitors can be hard to find but they are not that hard to build (I have made 2 of them for 2 different loops) A careful search of the Internet will find the plans for building one.

Another thing that may or may not be known is that you can nest a small loop inside of a larger loop with no apparent loss in performance providing that the loops are oriented at 90 degrees to each other. In that case each loop is in the plane of the null in the other loop which allows either loop to work.

To test this, we (I and VE6BEK) built 2 loops (The large loop covered 40 meters to 20 meters and the small loop covered 17 meters to 10 meters. The large loop was 62 inches in diameter and the other about 30 inches in diameter.) and tested them each separately then as an experiment we nested the small loop inside of the large loop and checked the SWR which had not changed significantly on either loop.

As for on the air tests -- well we all know what the bands have been like and there was no propagation on 10 meters but I did make a solid 5/7 contact on 15 meters into Pennsylvania with the loops sitting inside of my 2 car garage and the loop being used would have been about 5 feet off the floor to the center of the loop. We had no other antenna to compare the signal against so take that for what it's worth but we were quite ecstatic at the performance. Unfortunately 15 meters is seldom open to here lately so no more contacts were made and the radio we were using for test purposes was a TS-520 which did not have Warc band s so there was no possibility of our having tried 17 meters which often does have propagation.

The magnetic loop exhibits a very high degree of rejection to signals that are precisely at 90 degrees to the plane of the loop so that may be why it works. Ed, VE6BEK, went home to Alberta and built an extremely nice setup with one loop nested in the other and he made a rather intricate connection so that with a single steppir motor he could tune both of the loops. He used this on the balcony (4th floor) of the apartment he lived in but has since moved and has no antenna up currently. But he found the same thing as we had at my location, that the small loop inside of the large loop worked well.

His antenna gave him complete ham band coverage from 40 meters to 10 meters. And it occupied about 5 feet of floor space. For those hams with restrictions on antennas or limited space this is a very viable alternative and sure beats not being on the air at all.

I am very much an advocate of the magnetic loop. I currently have minimal restrictions on antennas and have a full sized Delta loop for 80 meters that outperforms my magnetic loop when band conditions are good (and I'm sure it does when transmitting at any time) but the magnetic loop really excells at reducing static and I would not be without it for receiving. Just this morning I was forced to copy signals on the magnetic loop because I just could not hear the other stations on my other antennas. I would then switch to the delta loop to transmit. Fortunately the static affects only the receive and not the transmit. HI

I have thought of that Jim, even with using 72 mhz equipment but the cost of the servo tester and the 3 wire cable was much less so the cheap part of me won out HI.

I also have found that the servo motor has to be de-energised when transmitting or the high RF field causes it to chatter violently. That might eliminate the use of wireless control or in any event make it more complex.

I was thinking of replacing the off/on switch on my servo tester with a momentary push switch so that I would not have to concern myself with remembering to shut it off when I go to transmit. As a rule I leave it off anyway unless I am tuning.

Simply place a switch in the + lead going to the servo's red lead.
You don't need to turn the tester off.

Back to the robotics kits... the ones I had seen used standard R/C
servos, but everything was powered from a port from the computer.

Sometimes an optocoupler (to trigger an op amp, used as a buffer)
must be used with long leads on the signal wire, but I think that has
more to do with the R/C receiver acting up than the servo itself.
Without a receiver, no problem.

The Tower Hobbies TS-53 is well up to this task.

http://www.towerhobbies.com/products/towm4500.html

Price is $10.00 USD

If you look at the photo, the output arm assembly is easily removed
with the small phillips screw. The shaft is splined. Easy
connection with a piece of stiff rubber or vinyl tubing to the shaft
of a capacitor.

> Does Shortwave (incoming signals) go thru houses - walls?

Yes, if they aren't metal.

Metal frame houses (metal where there used to be 2-by-4's) do tend to block or reduce signals whose wavelengths are larger than the openings between the frame pieces. Most "shortwave" HF signals are larger than the typical home stud spacing, so they might be blocked if that construction is used. Bricks and cynderblock may reduce signals somewhat, but not entirely.

> 2. What is going to happen to all frequencies after FEB.09
> who would be using them?

I, for one, am kind of confused about this, because it was my impression that TV stations were mainly changing over from one form of modulation to another, using the same 6 MHz spectrum space for either. In the interim (today) you do have many TV stations consuming two channels simultaneously, typically their original VHF (or perhaps UHF) one for NTSC (analog) and a temporary UHF one for digital, and they would be relinquishing the temporary one after the full changeover in Feb., going back to their original channel assignments exclusively.

Bit by bit, though, large chunks of the original UHF-TV band have been "sold" off from the public interest to private concerns over the last few decades, and I think that continues. Some of this space was sold for business use, some is used for public service (police/fire), etc. So the spectrum space gets divided up and sold to the highest bidder, whoever that may be.

There was a time when the FCC was in charge of enforcing the notion that the airwaves were a public resource and would be used for the public good.

Not sure what this has to do with loop antennas......

5837. Loop Antenna Preamplifer Circuit

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-16 21:57:24 UTC
From: Adam E.
Topic: 5837 Message: 5837

I have my old loop antenna just for the LW band, but stormwise had the nerve to take down the schematic diagram for the basic loop antenna preamp that just runs on 1 1.5 D cell battery. I am looking for a good well performing loop antenna preamp circuit, but easy to build. The reception in the apartment is bad because I don't have a ground rod or permission to plant one outside so I must use a loop antenna or an active antenna. The variable tuning capacitors are getting hard to get cause they are going up in price.

From: ka7nwq
Topic: 5839 Message: 5839

Hello to all. I had a few questions that I hope the group might be able to answer for me, or at least help me out.

I will have, here shortly, a lot of room to do antenna stuff. Basically, about 40 acres of farm land with the house / shack located on the front of it. I dont have a whole lot of trees around, and the ones that are there are maybe 20 to 30 feet high.

I would like to have 160 thru 6 coverage. My question is what type of antenna would you use if you had all the room in the world, without any high supports?

I would also like to play on 160 this winter since we are going back into the new solar cycle. Vertical vs loop vs low dipole? What type of receiving antennas would you use?

Thanks again to all who respond. Best to you and yours.

How about an inverted discone? There's a patent for this, though I have lost track of the number. The design was for army HF communications.

I'm having a bit of trouble understanding exactly what you mean.

In a nutshell, though, any piece of conducting material works as an antenna, though some are better than others.

The first rule of most good antennas is that the total size (length) is comparable to the wavelength of the signals being worked; which is why a half wavelength long dipole is a good starting point.

For HF frequencies, most antennas are based on using thin wires, partly because they are easier to analyze, and consume less metal. Thicker wires and pipes and such, in addition to being mechanically stronger, tend to have somewhat wider bandwidth, and lower losses, so they may be preferable in some cases.

The width dimension is a comparatively less important parameter, usually being a second-order effect, unless you are in the realm of very high losses. High losses are a problem with antennas that are electrically very small, which is why small HF transmitting loops are made out of pipe rather than wire, to keep the loss resistance down.

I don't quite follow the multiple rings idea I think you are suggesting; but I suspect one long pipe may be better than (or at least just as good as) several separate rings.

The one that I had in mind is US Patent #3701159, "Discone Antenna".
It's actually a Canadian design, and the patent expired back in 1989.

Hi Scott. Interesting (hypothetical) question; what is the best antenna on HF (all amateur bands) given all the room you need, but limited height. For the most part antennas are divided into 2 main categories ..... balanced such as dipoles and loops .... and unbalanced .... those antennas that work against some sort of ground, ground plane, etc...

I assume you want an antenna that will allow some DX which requires a reasonably low angle of radiation. I would choose an antenna that works against ground
since you say you have a lot of ground and no height to speak of. Dipoles and loops require some reasonable portion of a wavelength of height in order to provide a reasonable angle of radiation.

The key to good radiation from a vertical is a good RF ground .... eg up to 100 1/4 wavelength radials (at the lowest frequency) With such a ground system a 30' height vertical could be easily tuned at the base on all bands and put out a dynamite signal. The vertical could be designed a number of ways ... eg as a folded monopole, a top hat ... etc .... but performance ultimately depends on the ground system.

Most people don't have such a ground system because they don't have the space or they don't have the time or energy to bury all that wire hi hi.

In any event, that would be my best all band antenna given low height and lots of space.

Before someone misunderstands ... what I meant by "based on," is simply that most antenna designs are BASED on antenna theory as it applies to thin wire antennas ... NOT that most antennas actually use thin wires. Many antennas intentionally use thicker elements but often the assumption is that they behave like their thin wire equivalents, with certain known differences.

Back before the days of computers, it was moderately easy to calculate the effects of thin wire antennas, but extraordinarily difficult to do this for thicker elements. Even with computers, thicker elements can be tricky to analyze correctly.

Wow, a discone for 160 meters, I'd like to see that!

A properly designed and built discone can be a very wideband antenna, so it might readily cover the upper bands for you, perhaps supplemented by one or more other antennas for the lower HF bands. On the other hand, discones are not known for having particularly good antenna gain (they nominally have no gain).

The discone I had in mind (US Patent #3701159) is an interesting configuration. In this one, the ground and ground radials form the disc and the cone wires are the radiating element. An advantage of the discone over a "conventional" vertical is that the launch angle is lower plus you have wideband operation without the need for an overly elaborate antenna matcher. It is, of course, an omnidirectional antenna.

5852. trying to make a loop antenna to catch 10 khz signal

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-19 02:37:12 UTC
From: Subrat Nayak
Topic: 5852 Message: 5852

I have to make a 10khz signal receiver.. All might be knowing that an invisible dog fence works at very low frequencies compared to normally used radio frequencies.. SO, here we are there is a long wire transmitter carrying 10khz (9.8 to 10.2 khz) signal through it.. i got to make a receiver that senses the field and approximately tells the distance from the transmitter wire..

I figured out that for such loq frequncies, its not possible to make very very long whip antenna and hence loop antenna is a solution, but am not sure how to start off making one.. after that using the opamp band pass filer knowledge that i took from course work, i though a 10khz narrow band pass filter might suffice to pick the signal, then a some kind of peak detector might be able to tell me the signal strength. the signal strength (amplitude of the voltage on output) decreases with increase in distance from the transmitter. So i should be some way able to approx estimate the distance from the wire transmitter..

Now , correct me if i am wrong somewhere.. i have no idea about tuned circuits and not sure how they work and if i should use them or not. I mainly need help in designing the loop antenna for 10khz and then to make a tuned circuit for 10khz...

please respond..

Yup, I figured that.

> What i was saying is wooden dowel let say 24"
> then have copper rings place them over the dowel
> how many I don't know and then attach wire to each ring then to my radio.

The dowel just holds it together, it doesn't do anything electrically.

As I think I said before, I don't know what having the antenna broken up into several short rings does; presumably each one is a lot shorter than a wavelength. But I'd think it would work better with one long continuous piece. Then the current doesn't need to zig or transition back and forth between rings and wires.

If you meant using a separate wire from each ring back to a common feedpoint and then to the radio, that seems kind of bizarre and I don't know what it would do.

Hi Subrat,

I will encapsulate what I think you are trying to do .... if I am wrong
please correct me. You wish to design a RF detector that is sensitive at
10kc and has a signal strength indicator. I also assume it should be
'hand-held' and portable, since I can't imagine wanting to sit at home and
listen to dog fences hi hi. Similar RF detectors exist for other purposes
.... for testing microwave ovens ... or as a 'field strength meter' for
testing VHF antennas, etc..

In these cases the antenna is very small ... in fact they are often called
a 'RF probe' rather than an antenna. I would suggest the receiver would be
a simple TRF ... Tuned Frequency amplifier and detector ..... the input
would be high impedance with a small probe like antenna. I don't think the
probe need be a loop. The indicator could be a small meter or several LED
indicators. The tuning would be rather broad and would certainly work

across say 8 to 12 kc. Such a receiver would indicate a 10kc source as you approached it (dog fence) .... and the indicator would show and increase in level as you came closer. When you moved away it would go down ... and to zero once you were say a 100' ft away .... a matter of design.

Jim, VE3CI

There's a group of people who routinely "listen to" signals down in these low frequencies and below. One Yahoogroup where some of them meet is http://groups.yahoo.com/group/ulfelf/ . Those folks look at seismic events, the earth's resonant frequencies, etc., as well as Russian and other ELF communications down there around 10-25 kHz.

You can use either a short e-field (wire) antenna or a coil antenna. The ELF folks seem to prefer the coil variety (for noise reasons, I think), although NASA had a 0.3-20 kHz receiver for a 2-meter-long wire antenna. Those coil antennas can be compact, using ferrite cores.

Be aware that some of those guys are looking for extremely weak signals from around the world so their antennas might be more complex than you need ("Black Hole" antennas, "Negative Resistance" antennas).

A simple "loopstick" (coil on a ferrite core) might be all you need, tuned to resonance with some capacitance. I'm guessing that's what the dog collars use.

Andy

Thanks Andy,
Sounds good.. am going to wind some hundreds of turns of wires on a ferrite core and see if i can get a capacitor connected in parallel to pick up 10khz.. I need a simple one so that i can sense the dog fence from 3-4 feet and get a signal inversely proportional to distance.

Hope i dont catch a NASA signal or some signal from outer space (kidding!!!) thanks again..

regards,
subrat nayak

I don't know if the signal versus distance is that predictable. For one thing the transmitting antenna is a much larger loop, and you are well within its "near field." Would be interesting to see what you find out.

I may have erred somewhat by referring to a "ferrite core." What I really meant was "ferrite rod," which is a bit more specific, and means you shouldn't use a toroid core or other circular core, which tend to support self-contained magnetic fields rather than external ones. You can get loopstick antennas (wound on ferrite rods) from discarded AM radios.

The NASA VLF-2 and VLF-3 receivers were designed as instructional tools, for ordinary citizens to listen to various natural atmospherics such as "whistlers," "morning chorus," etc. Doesn't have anything to do with space or anything NASA was sending into it. It was part of plain old science, which is something NASA used to support before G.W. Bush secretly rewrote their charter.

I'm guessing the copper rings are also 24" diameter, and the dowel is
a support for them? Otherwise, I'm not seeing it. A quickie sketch
posted to the files section would help us to visualize it.

From: Matt B.
Topic: 5860 Message: 5860

I can't seem to find simple or easy to find answers to this.

I want to build a loop with the tuner located at my home stereo where I do my listening.

it will be AM loop, perhaps using the great designs of Chris Trask and one other here in the Files section where the gentleman used a motor on the variable cap mounted outside on the antenna.

I understand that adding extra capacitance will greatly affect the tuning and so many loops have the capacitor mounted on the antenna or its base.

However, commercial pre-selectors/tuners, are REMOTE.
The unit is connected by the feeder line from the antenna into your home where the tuning unit sits.

I'm thinking along the lines of a MFJ 956 type unit with main tuning capacitor and 4 or 5 inductance loops to create more narrow and selectable bandwidths.

Why can't we just build the same type of units and hook them up to outside loops for AM BCB?

Thanks
Matt Bourdeau

I wouldn't recommend that remotely tuned loop for receiving as it was intended for 100W transmitting applications and tunes a single band, in that case the 40M radio amateur band, and it's a bit expensive and complicated to make for just receiving purposes. For receiving, I have another design available that is far less expensive, uses varactors for tuning, and which tunes from 5.5MHz to over 12MHz:

http://www.home.earthlink.net/~christrask/Paper011.html

For AM BCB reception, you would only need to increase the diameter, use multiple turns, or both. A 1.5m diameter loop having three turns with the turns spaced at least five diameters apart would probably work, as would a 2m diameter loop having two turns.

The reason for using remote tuning in loop antennas is that the antenna impedance is primarily an inductive reactance, and connecting an antenna such as that to an antenna tuner through a long length of coaxial cable (or other feedline) will result in substantial losses, which will reduce the signal strength at the receiver and increase the noise figure.

Hi Matt,

There are very different limitations and restrictions on loop manufacture between those used for transmitting and those used for reception only. When using a small loop it is very desirable to resonate/tune the loop as it results in a narrower pass band and increased signal voltage. If the loop is remote and is intended for xmission then the tuning should also be remote (at the antenna). However if the loop is used for reception it is very possible to connect the loop by a feed line to a tuning unit at the operating position.

The possible distance between the loop and the tuning unit depends on the frequency of operation and the type of feed line used. Coax can be used but is limiting due high capacitance. I also prefer balanced feed line for this reason and it is generally less susceptible to local RFI. If the loop is for HF then the distance possible is only 10' to 15'. However, for

MW the distance can be much greater. I would use 300 ohm TV twinlead feeding into a home brew balanced tuner. The tuning range would be reduced since the 300 ohm twinlead feed line will introduce a substantial fixed capacitance.

I have used this system for both HF and MW. It is not commonly used ... at least I have not seen it mentioned in loop discussions. I have not seen a commercial balanced antenna tuner for MW either, although it is not hard to build one .... it would look a little bit like a crystal set ... without a detector hi hi.

Jim,
Your comments come at a most appropriate time as I am constructing a square MW loop with 4ft sides to sit on a rotator in my loft.
I would like to be able to tune the loop at my operating position which is in the room below
the loft.
This would mean a feedline of some 10ft long to the point where the rotator control box is situated.
I would appreciate any comments / suggestions you might care to make either via
the list or direct.
Many thanks,
72, Brian, G0NSL-QRP.

I'm a little puzzled now!

If a transformer unit will be used on the Loop, why should it be "tuned"?
If you have a Preselector, active with an Amplifier or passive without one, where will the "remote tuning" come in? If the Loop will only be used for receiving, is further manipulation of impedance any more so important?

It is another case to turn the Loop with a rotator. Then it will not be too important, if you have a rather long cable with three lines to electrify the rotator and send commands to turn the Loop and stop the movement. I have one on my house on the lower roof. I am using an extra coaxial cable to feed the radio signals into my receiver from my small Flag-Loop. My cables are about 15 to 25 meters long.

It is different with my Datong AD-370 miniature Active Dipole. With it is used only a coaxial both for sending electricity into the main unit and RF signal back to the receiver. I could have used the Datong with my rotor, but because its two rods were broken during my move to Spain, it would be a little difficult. I am using it with wires of about 2.5 meters each. The original 2 steel rods were 1.5 m long each. Perhaps later I will test the datong with the rotor using a different construction (?). Maybe using 2 telescope-antennas of 1.5 m. Depending on the place, where you live, Datong is a quite good mini-active-dipole... For years ago Finnish DXers reported a lot of Latin-American stations using it in suburbs and even towns over high houses.

More questions:

How much "gain" will be lost by using a "non-resonant" wide-band (all-bands) antenna instead of a one-band "resonant" antenna? I never saw any figures anywhere... It seems to me, that many theories are used mainly for the benefit of the "professionals". I am interested to see real measured figures, not just mathematic calculations.

Professor Mike Underhill, G3LHZ, has shown, that "Formulas" and "Simulations" have made people believe in half-truths, wrong theoretical opinions about Loops.

In the book, International Antenna Collection, pp. 229 to 246, he states, that "The Truth About Loops" is in practice very different, than the former widely accepted "truths".

"...the simulations and ancient formulas can be as much as 20 to 30dB in error as compared with the 'truth' of the real measured results."

"There is also a lower absolute limit of about 50 cm, or 25 cm, respectively, for single-turn transmit and receive loops."

"Square, hexagonal and octagonal loops behave almost exactly the same as ech other if the perimeters are the same."

"The unidirectional loop has a greater directivity than a half-wave dipole by 2.62dB. This means that the loop only need be 77% efficient in order to have the same gain in the favoured direction as a half-wave dipole at the same height and in same position!"

""No aerial is better than the envirenment in which it is placed.""

I agree with the professor:"There is still a lot more to be learned."
Test, test, test and test more to see, if things work in use, not only in peoples' imagination.

Hi Brian,

With the 4' MW loop directly above you, approximately 10' away from your operating position there should be no difficulty in simply connecting the loop to the tuning capacitor at the end of the balanced feed line. I recommend 300 ohm twin lead for its convenience and ease of installation .... 450 ohm ladder line will also work and it will introduce less feed line capacitance but it is more awkward to use. This arrangement simply tunes the loop (5 or 6 turns ??) to the MW frequency of choice.

You will also need to consider how you will couple the loop to your receiver. I will simply assume your receiver has a low impedance unbalanced input (designed for coax). The customary method of coupling is to include a second coupling loop (1 or 2 turns) inside the tuned loop and connect this 'pick-up' loop to the radio with thin coax. This is the easiest and most straight forward method .... however you have 2 lines coming to the tuning position (3 lines if you include the rotor cable).

It is possible to by-pass the pickup loop all together and couple the loop directly at the point where the feed line comes to the operating position. Instead of simply connecting the tuning capacitor use a 'tuning unit' along the lines of the z-match to do dual duty .... both tune the loop and couple it to the radio. This is what I do on HF ... remotely tune

and couple the radio to the loop with a z-match.

There are plenty of on-line sites demonstrating the construction of z-match tuners (at hf). there is no reason this can't be applied to mw. In the meantime you could simply use the 'pick-up loop' solution.

Not to be confused hi hi

The question was, I believe, can I tune a small receiving loop remotely? I said yes, the hard way (usually required if you are transmitting some power) by using a remote motor of some sort to tune it at location or the easy way by bringing the loop feed point to the operating position with feed line and tune it there. the second way is possible given the limitations of distance due to introduced capacitance in the feed line.

You mentioned feed line .... it is possible to both tune the loop and couple to the loop using the same feed line. This requires terminating the feed line at an antenna tuner/coupler rather than simply a tuning capacitor thus eliminating an additional cable. I suggested the circuit in the well know z-match can accommodate this function.

Such a circuit (z-match) is I suppose a 'transformer' in that it converts balanced feed to unbalanced feed and high impedance to low impedance (50 ohm for the receiver) while at the same time tuning the loop to resonance.

The loop is a small loop tuned to resonance ... eg I believe he said 4' square and in the Mw band. The loop you mention ... the flag-loop is another kettle of fish ... and is i believe a kind of terminated antenna along the lines of the k9ay loop.

That is 100% absurd, not to mention grossly misleading. I only just made mention of a varactor-tuned receiving loop design of my own on this list, and you're now misleading this fellow by claiming that you can only tune remotely with a motorized variable capacitor?

Did you just join this list, or do you have a reading comprehension problem?

You can complain all that you want, but you are still making grossly
misleading and extremely inaccurate remarks concerning the remote tuning of
antennas, and it's not difficult to see here that you are avoiding the
comment about using varactors for remote tuning.
```

Why are you stating that you can only use a motorized capacitor?
Perhaps you should take the opportunity to explain this to all of us.

We need to clear up the misinformation that you have been given on this subject.

First of all, the impedance of a loop antenna is best represented by a small resistance in series with a rather large inductance. For a 1.5m diameter loop made with 1/4" diameter copper tubing, this equates to a resistance of about 3 ohms and an inductance in the order of 2.7uH. If you were to connect this to a 50-ohm receiver (or coax feedline), you would experience a signal loss of around 24dB. Using a higher impedance feedline only makes the problem worse.

In the design that I posted to this list recently, I used a pair of varactors to remotely tune the antenna, using a bias tee to provide the tuning voltage through the coaxial cable. With a series of matching transformers, the antenna impedance is brought up to the desired resistance of 50 ohms and the signal loss is less than 1dB.

You should ignore any comments about needing to use a motorized capacitor for tuning receiving antennas, as that is thoroughly false and misleading. You only need to use that approach if you are using the loop for transmitting, as I and many others have shown in a variety of designs. The way that I designed the remote tuner with balanced tuning for a receivng loop results in far less distortion than the usual single-sided approaches, such as the one I described in my 2-part series on remotely tune receiving loops in QEX a few years ago.

The paper describing the varactor-tuned loop antenna is at:

http://www.home.earthlink.net/~christrask/Paper011.html

and my approach to the transmitting loop with a motor-driven capacitor for tuning is at:

http://www.home.earthlink.net/~christrask/Paper012.html

The only difference from what I did with the varactor-tuned loop and what you have for MW reception is that the resistance and inductance of your antenna will be much larger, which means that you will need a lower ratio in the transformers to match the real part to the feedline and you will need to use two varactors in parallel in place of the single varactors that I used so as to get the tuning into the MW band.

Hi,
Many thanks for the input on the ' remote ' tuning of my proposed MW receiving loop antenna.
It would seem that the tuning is not a problem, it is the extraction of the signal via the two turn inductive winding as any additional length i.e. feedline, between the loop and the Rx
will upset the balance.
Obviously I need to investigate further.
Adding the required feeder length to my free standing loop which is on a camera tripod in the shack should simulate the loft conditions and give me some idea as to what happens.
Regards,
72, Brian, G0NSL-QRP.

Subject: Re: SHORTWAVE
From: steve##hi.com (Steve Byan)

I heard that the signals can thru houses than this comes along

I have a 1992 Radio Shack DX440 Shortwave radio. It was the best when I bought it. However, I need to find a relatively simple was to make a powerful antenna that will allow me to pick up stations.

Get an "RCA phono plug" from Radio Shack. Attach 50' of stranded hookup wire (#18 to #22 guage wire is best from a mechanical standpoint - makes no electrical difference) to the center pin of the phono plug.

You may need to have someone solder this connection for you - I don't know if Radio Shack has a solderless RCS phono plug.

Insert the phono plug into the external antenna phono jack located on the back of the DX440. Move the antenna selector switch located next to the phono jack from "internal" to "external" (my memory may be failing me here - I think the DX440 has an internal/external switch. If it doesn't, then don't worry about it.)

Run the wire as high and as long as possible. Preferably get it outside, as shortwaves don't
penetrate houses very well. An sort-of upside-down "L" shape like th

I have a 60 ft guyed Rohn 25G tower that I would like to use to support one end of a 160 meter full wave delta loop. The other two ends will not be very high, around 30 ft off of the ground. I have a heavy duty 15 ft pipe attached to the very top of the tower so this corner will actually be about 75 ft off of the ground and this will be the feed point. I am wondering if anyone else is using a 160 meter full wave loop not just on 160 but on other bands as well. I have the loop cut for 560 feet from using the old formual 1005/f in mhz = length in feet, I rounded it up to 560.

I have the old B & W 450 ohm "open wire" feedline that I will be using. Just wondering what the comments are on how this operates on 160 (I know it will be very low) and on the other bands as well.

The main xmit and rcv ant right now is a half-sloper around 130 feet long, fed at the very top of the tower (at the 60 ft point). It actually works very very well but I am just curious to see how the loop with do against the sloper, which is my reference ant for 160.

Please "reply to all" since I can not access my Yahoo account from work during my lunch break time, thanks!

Date: 2008-10-28 16:06:15 UTC
From: Jeff
Topic: 5886 Message: 5889

For DX work U want the loop legs as vertical as possible.

Also, the most effective feed point is a 1/4 wave down
from the apex or at the corner leg and baseline.
I use a 1/4 wave matching stub of 75 ohm coax to my
50 ohm coax to the shack. (easier to feed)

The apex can be just a few feet off the side of the tower.

The closer the baseline is to the ground (not less than 6')
the better SWR U can achieve.

The antenna will slightly favor signals broadside.

I use a full wave loop on 80 with great results.
(also use it as a listening antenna on 160 sometimes)

Have U ever considered linear loading your tower
for 160 ?? I have a tower and this works very well.
This will be a little noisier but a better radiator
for transmitting. Your sloper is going to probably
be better for transmitting due to the vertical element.

Hope this helps,

Jeff - NE0DX

From: lane zeitler
Topic: 5886 Message: 5890

Jeff, thank you for the info. This ant will be a horizonal loop, delta shape, highest corner fed at around 70 feet, other two corners at around 30 ft, not very high at all. I expect to have it up this saturday. Wire is already cut to length (560 ft), open wire feed is attached. Just need the time now. Thanks again.

From: DAVID
Topic: 5891 Message: 5891

hi i use a single turn loop 6 feet high 10 feet long fed in one corner with a 48/11 turn balun and in other corner a variable resistor. it works amazing from 500 khz to 1600 khz but from 1600 - 1700 khz it just stops dead then it picks up again on the 160m ham band. i have 2 loops same dimensions and both are the same. there is some usa etc stations i would like to receive from 1600 - 1700 so any ideas whats happening ???? thanks david h .... ayrshire scotland

5892. 160 horizonal delta loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-30 10:27:08 UTC
From: lane zeitler
Topic: 5892 Message: 5892

I am just about ready to climb the tower and hang the 160 mtr delta loop. It is 560 feet long overall and will be a horizonal loop, triangle shape, fed in one corner with ladder line. The feed point corner will be at 70 feet, the other two corners will be at 20 feet and 30 feet. I am not expecting this to outperform a very good working half-sloper with the feedpoint at 70 ft but expect the receive noise and receive performance to beat the half-sloper. I would also expect a large, horizonal loop like this to offer very good overall performance on the 20 to 10 meter bands. Anyone else using a 160 mtr full wave horizonal loop on the upper bands? Lane Ku7i

Please cc my military email address above, thank you.

Date: 2008-10-30 15:21:14 UTC
From: Rob - W1AEX
Topic: 5892 Message: 5893

I used a very similar antenna, with roughly 510 feet of wire, horizontally arrayed, with the feed point at 65 feet and the two other supports at roughly 40 feet. It was a high angle cloud burner on 160 and 75 meters, making it an ideal antenna for close-in work in the New England area. It was a very quiet receive antenna on those bands. For medium range work a simple dipole outperformed the loop by a considerable margin. On the higher bands, I had nothing to compare it to at the time, but the pattern was very complex and unpredictable. Again, a simple dipole would have probably outperformed it on any of the upper bands.

I'd love to hear how it works out for you.

Rob W1AEX

5894. Wire and Cable for Sale - Must Go due to selling of home

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-30 17:26:31 UTC
From: denisnh
Topic: 5894 Message: 5894

Hi All. Due to a series of personal setbacks, I am forced to sell my home. I am currently moving all my stuff out and am selling off as much as I can.

I have several rolls of new, unused wire. Some of it is industrial surplus, but it is all in new condition. I did NOT get this stuff free, so I'll sell it for the lowest prices I can. The price per foot is still much lower than anything surplus or otherwise you'll find anywhere. If you do find the following items for less money, please let me know. I have just posted this wire on Craig's List under the links below.

Right now I have two types of wire for sale:

1) 12 ga. PVC jacketed copper stranded, ideal for just about any type of wire antenna.
http://boston.craigslist.org/nwb/mat/893796223.html

2) Military spec RG-58/U, 50 ohm coaxial cable also in new condition, never used.
http://boston.craigslist.org/nwb/mat/897230310.html

Shipping is available for those who don't live in the area, or it can be picked up in Billerica, MA.

Thanks,
Denis

Hi David !

My name is Milton, and i constructed the same antenna in paralel with an 460pf variable capacitor and i´d
added a couple loop in middle of your antenna but i´ve got a very low signal because i don´t have a preamplifier.

Would be possible to obtain a best signal with this antenna in passive mode ?

May you have a photo of the balun you used ?

Milton

single turn loop

Posted by: "DAVID" [22]dhamilton1@... [23]tvdxrools

Wed Oct 29, 2008 9:37 am (PDT)

hi i use a single turn loop 6 feet high 10 feet long fed in one
corner
with a 48/11 turn balun and in other corner a variable
resistor. it
works amazing from 500 khz to 1600 khz but from 1600 - 1700 khz
it
just stops dead then it picks up again on the 160m ham band. i
have 2
loops same dimensions and both are the same. there is some usa
etc
stations i would like to receive from 1600 - 1700 so any ideas
whats
happening ???? thanks david h .... ayrshire scotland

Dear group

The latest video offering from UKQRM is now on-line

http://www.youtube.com/watch?v=tKhl-1CRkkU

In this video we provide a simple non technical description of the huge problem of Power Line Transmission interference to Shortwave Radio.

Are you affected by this? Do you live in the UK?
If you can answer yes to these questions we need to hear from you!
Only by coming together can we stand a chance of preserving shortwave radio for the future.

Don't leave it to someone else, they are probably leaving it to you!

Check out the UKQRM web site for more details and how to join the UKQRM Yahoo group.

Regards

Mike

From: loopantennas@yahoogroups.com
Topic: 457 Message: 5897

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

5899. H Double Bay Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-11-02 13:27:58 UTC
From: lane zeitler
Topic: 5899 Message: 5899

Paul Carr N4PC did a great article in CQ sometime in 1995. The antenna he designed and built was called the H Double Bay antenna. Other articles have called it the Skeleton Slot antenna. It is essentially two full wave lengths side by side but share one common side.

Has anyone tried these? I am wondering if instead of being mounted in the vertical plane such as the article suggests if it could be rotated 90 degrees and put up horizonal?

The website link to his article is here:

http://www.wz4c.com/Hdoublebay1.htm

the bottom of the page will take you to page two, bottom of page two takes you to page three.

Re: Wire and Cable for Sale - Selling Home and it all must go.

The RG58 Coax is sold out. I'm going through my various storage
locations in hope I have more and will update this thread if I do.

Thanks to all who ordered or just had kind words of encouragement.
The amateur radio community consists of the nicest folks on the planet
and I'm proud to be a member.

Thanks,
Denis

Topic: 5901 Message: 5901

Since getting my ham license, I'm trying to work up a 1920s/30s shortwave receiver. I think this will make a good basic foundation to start with (my thoughts run along the lines of the battery-operated Super Wasp).

The inductance of the loop (2 turns of number 26) yields 7.09uH. The varicap mounted yields 12 to 365pF. I'm hoping to cover something from around 3 to 8 MHz with this loop. Later I'll be adding a tuned RF preamp, a regen detector and at least one stage of audio, all with late 20s/early 30s British tubes I used to have as a teenager.

Afterwards I have to work on building my transmitter.

This tuned loop will be the input to the first stage. I have the tubes on order for this project, they should arrive in about 3 or 4 weeks. The circuit is based on the battery operated Super Wasp design and this loop will feed the RF stage (Tetrode) directly.

I mounted the vari-cap near the loop so I wouldn't have lead length influencing the inductance of the loop.

This evening I added copper plate (just unetched PC boards) to the top surface so I can not only mount and solder components to it, I can also erect other pieces of copper vertically for interstage shielding.

There is no effect as the the reception depends mainly on vertical elements.

Hi Brian,

I assume a small tuned loop ... e.g. less than 1/10 wavelength in circumference. In the case of a tuned loop for MW I have built them circular, square, and rectangular and have not noticed a great deal of difference in performance .... eg sharpness of the null. The rectangular version I have built is not very far from square ... e.g. 14" x 12". I mounted this loop with the long dimension vertically. I have seen the tuned loop in an old radio with approx the same approx ratio of dimensions but mounted with the short dimension vertically.

Although I have built them in different shapes I have not experimented by doing comparisons. Generally speaking I have noticed the biggest difference in performance relates to size and quality of construction. A loop with 2' on a side compared to a loop with 1' on a side has 4 times the capture ratio. Also the kind of wire and tuning capacitor used makes a difference. That is it produces a higher circuit Q.

The null is perpendicular to the loop and I find that the null can also be improved by moving the plane of the loop angle as well as azimuth.

Having said all that all the best tuned loops seem to be symetrical but very good performance is possible with loops that are slightly off of perfect symmetry. The reason for being off is usually due to some building consideration like material at hand hi hi. By the way, I just found a piece of plastic pipe about 15" in diameter and I have been thinking about how I can turn it into a nice tuned MW loop hi hi. Building a good loop is as much a mechanical as an electrical challenge.

Jim,

Theoretically yes, but practically, it really doesn't matter. I have seen loops from circular to square and everything inbetween including a spider web design and they seem not to matter.

Do you think spiders might be secretly DXing?

Hi,

Most of the tuned loops I have built have been 'box' loops although I have built many 'inductors' for xtal sets that are spiral wound on circular forms with radiating slots. I weave the windings in and out of the slots. I often couple these inductors by mutual induction so it is advantageous to have them flat. However large inductors approach being a 'loop' and small loops start looking like 'inductors' hi hi.

5917. Loop Tuning Display

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-11-13 20:56:44 UTC
From: roodyjs
Topic: 5917 Message: 5917

I just completed a 40/30/20 meter copper pipe transmitting loop, and it works fine. I'm using the "trombone" type capacitor tuning (U-shaped coaxial copper pipes with dielectric covering the inner, sliding pipe).
My remote tuning involves a small DC motor turning a long brass screw assembly that then moves the slider in or out of the larger pipe. Works well, and I am using a kit built variable speed motor controller to control the tuning speed.

What I haven't been able to figure out yet is how to monitor the slider position remotely. Although, I can view the SWR on my rig, the Q of the antenna is high enough that unless the capacitor is already pretty close to frequency, it's very difficult to tell which way to tune the motor (up freq or down freq).

Right now, the only way to determine this is to run the motor all the way in one direction until the SWR comes within a readable range or until a limit switch gets activated. Then reverse the direction of the motor until the SWR gets into range.Full travel in either direction takes a couple of minutes.

Is anyone using a more accurate way to remotely show the capacitor position so the operator can easily determine which way to tune?

Thanks for any help you can offer.

I didn't see any answer to your question however you can find all the information you want/need by simply doing a search (google?) for magnetic loop antennas and if you are looking for other than a mag loop just refine the search. I could search for you but no doubt you have already come to that solution by now. 8>)

Jim.

You have found what the biggest disapointment with the trombone type of capacitor may be. I can only suggest that you might consider a motor that provides a higher tuning rate as well as a slow one for fine tuning or switch to a butterfly capacitor and use a servo motor or similar device.

My magnetic loop can be tuned from one end of its range to the other in a second. That capability also comes with a downside as well because the noise peak and resonance peak is very sharp and tuning for final, minimal SWR can be a bit of a pain, an issue that you won't have with the trombone I'm sure.

I wonder if one could use some of those magnetic reed switches (I think they were called) and space them along the length of the trombone. Then a magnet attached to the capacitor could be used to switch the reed switch and fire a led (in the shack ?) to give some indication of where the loop tuning capacitor is.

Then again when I think of it, wouldn't you be able to determine where the loop is peaked by listening on your receiver? (sure can tell with my loop) Then, let's face it, it won't take you long to learn which way you have to go to get to the band you are planning to use. 9>)

Hi Jim,

Myself and others have found the MFJ-259B Antenna Analyzer a
great piece of test equipment to use with a transmitting loop.
To start with it is very handy to use for setting up the coupling loop
or gamma match for best SWR.

You can quickly sweep the HF range to pinpoint exactly where
the loop is tuned, then tell which way to turn the remote tuning motor.
I keep my MFJ-259B ready to use to switch in-line with coax switches to
quickly tell where
the loop is tuned then to verify when the loop is exactly on the
desired frequency, then switch out the analyzer to transmit.

You will find lots of other good uses for the MFJ-259B but it is
dandy to use with a transmitting loop.

Todd,

I have the MFJ antenna analyzer and that's what I used to do testing
of my antenna. Never thought of just having it connected full time for
tuning. Makes me think of a way I can switch out my dummy load and
switch in the MFJ when I want to change bands.

Thanks for the idea.

Topic: 5917 Message: 5922

Garry,
I too have thought of using small reed switches with a 'traveling' magnet to indicate position. Since my connection to the capacitor tuning motor uses 3 wires, I may replace what I have with Cat5 cable (8 wires). This gives me an additional 5 wires to use for reed contacts - 40 meters, 30 meters, 20 meters, ground, and one extra for any other band or freq I want.

That way I won't have to search too far to know where the trombone is.

I looked into several pulse counter apps to keep track of motor turns, but nothing satisfactory yet.

Thanks for the note.

How about a linear travel potentiometer on the trombone or a 20 turn pot on the back of the motor shaft.

I have read that it is possible to significantly increase the voltage rating and capacitance of an air spaced variable capacitor by immersing it in mineral oil. Would this approach work on a loop antenna capacitor?

Neil G7AQK

I think it would work but don't know how well. It will be
extremely messy unless you have the capacitor well-sealed
inside a leakproof container. Also I believe the capacitance
would not be as stable as an air-variable because the
mineral oil expands and contracts with heat and cold.
Someone will just have to try it and let us know if it
works!

If possible check the Q of the antenna before and after doing the
immersion to see if the mineral oil causes additional dielectric loss.

The dielectric constant of mineral oil is 2.1 so your capacitance should double.

Hi Neil

I guess it depends on the kind of oil used .... e.g. not the infamous PCB type hi hi. I am no expert on the subject ... but many years ago we used oil-immersed high voltage power switches (in the Arctic) for switching high line power sources. They of course shielded the contacts from wx and limited contact sparking and burn. They worked down to -40 deg C without difficulty. I am not sure whether they increased voltage rating ... however they seem to seal the switches from wx corrosion and burning (in the presence of oxygen).

>
>
Best viewed with fixed width font.

I did the test last night. Here are the results;

Value Before W/Oil
Low PF 7.3 PF 21.2 PF
Hi PF 175.1 PF 490.8 PF
Q Lo PF @ 1MC 759 803
Q Hi PF @ 1MC 890 890
Hipot DC 230 VDC 550 VDC
Hipot AC @60 CPS 159 RMS 389 RMS
Hipot AC 1KC 150 RMS 369.5 RMS

And yes, the test equipment I use is old, surplus stuff I've had for years, but still does the job.

I used an empty pickle jar and screw on lid with a hole mounted in the center to hold the panel mounted cap. I made other holes for connecting the leads (2) to make the measurements. The Hipot tester showed the test

set-up had a breakdown of better than 5KV, the max for my Hipot tester. The stray capacitance is measured at .5 lead to lead, and .7 pF lead to cap.

The oil is Walgreen's finest used for medicinal purposes, so I assume (Ass you me) it is pure. ;-)

Would I do this to use outside on an antenna? Yea, why not. Would I use this setup on an amplifier? No. I would get a vacuum variable. Did I have fun? Yup. Nothing better to do as there was nothing on the bands I was interested in, including the cable bands. 8-)

I have inserted both Teflon and Mica Sheets into variable capacitors with some measure of luck. I first saw this done in very small size large value variables used in broadcast radio receivers and it worked well.

cheers,
s.

Hi Neil,
Oil filled capacitors do work very well for high voltage. I work with these every day, with some up to about 40,000 volts. The major reason it does work is the elimination of corona in the air between the plates. So the first thing to do is removal of all air. For large plate spacings, this can be done by vibrating the capacitor to let the bubbles go to the top. For close spacing, putting a vacuum on the capacitor and then filling while under vacuum is necessary. The oil needs to be clean and pure, and moisture free. We use special transformer oil, which you might be able to get from your local utility. Multiply the capacitance of the air gap capacitor by about 2.2 when you add the oil. Breakdown in air is about 3000 volts per mil. In mineral oil, such as Shell Diala Oil B, it can be as high as 80,000 volts breakdown in 0.1 inches. At high frequencies breakdown characteristics get a bit more complex. Another consideration with loop antennas would be the dielectric losses in the oil, which will be greater than in air, so the Q of your loop might go down, reducing the sensitivity.
Regards,
Paul

The oil filled capacitors I've seen were used for HV supply filtering, where dielectric losses don't matter.

Are they also commonly used in other applications? With either pulses or RF power where dielectric losses are important?

Anyone have any experience with vacuum variables?

From the pictures I've seen the leads to those devices seem quite small.

Folks go a lot of work to use large diameter copper tubing and
minimize solder joint losses.

What sort of Q do these VVCs have at HF?

Hi Jim,
I have had some experience using a vacuum variable with a transmitting
loop and I would not recommend using one unless you could solder or
braze the leads to the capacitor. Clamp-on or bolt-on joints are to
be avoided in a transmitting loop as they are unreliable.

That seems to be one point all the articles leave out when promoting
the use of a vacuum variable for a transmitting loop. Rule number one
for a transmitting loop is that all joints or connections should be
soldered, brazed or even welded. So why would anyone recommend
using a vacuum variable if the only way you can connect to one is to
use a clamp-on or bolt-on connection?

My experience with a vacuum variable is that after only about a week
outdoors the clamp-on connection would begin to deteriorate no
matter how tight the connection or how weatherproof it looked.

No one seems to know if you can solder or braze a copper strap
onto a vacuum variable without destroying the seal or possibly
cracking the glass envelope due to having to use high heat.

I recommend building a trombone-style piston capacitor using
Teflon sheet for insulation. I have tested a home made piston
capacitor with Teflon insulation on a Hewlett-Packard Q-meter
and it had higher Q than a vacuum variable! So no need to
spend big bucks on a vacuum variable that won't work well
in a transmitting loop due to having to use an unreliable
clamp-on connection.

Todd

That's pretty much what I was worried about. I'm for now just doing a single band antenna so my capacitance variation is only a couple of pf around 20pf nominal.

I'm just doing an "overlap cap" where the ends of my 2" copper strap will have U shaped intermeshed ends forming a 4 plate cap. Makes for a small physical area which should be easy to package. Details tbd.

No solder joints anywhere so this should represent max Q for comparison to any other configs I try.

Hi Andy,
We do use the oil filled capacitors in RF applications for very high power transmitters (up to 2 MW), although the frequencies are generally under about 200 kHz. In this application, dielectric heating has not been a problem. We also use oil filled capacitors and transformers in high voltage pulse applications.

Hi Jim,
Do not apply any heat to the vacuum capacitor. Brazing is not an option. The connections must be made with clamping bands or threaded screws if the cap is drilled and tapped for bolted connections. Heat can destroy the capacitor by breaking the vacuum seals or destroying the delicate copper connections within the cap. I work with these every day. For exterior use, keep it in a protected environment, and on the connections, apply a very light coating of something like WD40 to the connecting surfaces before tightening the connections. The pressure will displace the film.

Rather than WD-40, let me suggest Corrosion-X. Google will find vendors for this product. We use it on electronics offshore in saltwater environments. It works just like it says, and very well. We spritz all over switches, transformers, cards, connectors, everything.

Corrosion-X is used extensively on aircraft, too.

Hello!

Is it possible to use a SWR-Power Meter, possibly with some modification(s) for receiving-only purposes?

I happened to buy one for years ago at a flee-market, but didn't realize, that it was made for Radio Amateur use only... How stupid from my part!

Now I would like to try to benefit from this SILTRONIX Model FS-113B, which has 3 analog meters on its front panel, one for Modulation, one for SWR and one for POWER.
I received this meter in package with Instruction Manual and in Mint condition, probably very little or totally non-used. It seems to use only two potentiometers, probably in connection of some (6 total) diodes? No other mechanics than three toggle switches.
Frequency: 26-28 MHz. Meters 100uA F.S.D. Dimensions 200x100x140mm.

Surely I could cannibalize this nice box, take the front panel with meters away and put on a new panel with for example innards of a home brew preselector and switchable in/out connections for many antennas and many receivers... But what about trying to build a simple recieving antenna analizer with analog display or even a digital display? I just saw one kit sold by Norcal, which seems to be very cheap, as it is very simple, too.

With these thoughts I remain waiting for your advice and suggestions or experiences of similar or different handlings.

73,
Ami

Hi Ami
It is not possible to use that instrument for receive purposes.
You would be better off to sell it and recoup your money then invest in an antenna analyzer. Good ones are not cheap but well worth the money. Check out MFJ for details and prices - you might find a second hand one.

Google is probably your friend here. If your receiver does not have a
built in signal meter - you may find a circuit to help you to connect
one of those meters to your AGC line.

Hi Ami
It is not possible to use that instrument for receive purposes.
You would be better off to sell it and recoup your money then invest in an antenna analyzer. Good ones are not cheap but well worth the money. Check out MFJ for details and prices - you might find a second hand one.

Google is probably your friend here. If your receiver does not have a
built in signal meter - you may find a circuit to help you to connect
one of those meters to your AGC line.

Hi,

Yes, it could easily be converted for receive purposes ... but then it would be for a unique purpose. To measure relative signal strength of local transmitters. A useful device if u were going to test the radiation pattern of a transmitting antenna you might be building or adjusting. These signal strength meters were common in radio shops that repaired mobile radios. They would be about the size of your meter. It would have a plug-in whip antenna (1m in length approx.). The whip would terminate via an inductor of some type. A simple diode detector is used to rectify the RF across this load and the resultant DC current would deflect the meter movement.

It would be categorized as a piece of test equipment rather than a receiver of receiver aid.

I second that. WD-40 is not an oil. It will evaporate in a short time
after washing any oils or waxes away and make it worse than before. I
hate the stuff.

I always hated it when a piece of equipment would come in with the
stink of WD-40 on it.

From: gmcjetpilot@yahoo.com
Topic: 5946 Message: 5948

BBC has been dropped. Why?

Well because of:

Internet simulcast
internet podcast
satellite radio
local broadcasters carry their programs.

In my area I can get BBC on broadcast TV and Radio through PBS (public broadcasting).

I get BBC America TV which has news and entertainment 24/7 on digital cable TV. I like the news when I get a chance (interesting to hear a forigen report of America)

My favorite BBC America program is TOP GEAR, an hour car show with lots of humor. The production values are very good. They often go all out exotic street sports cars on their track. My cable provider even has "on-demnad" BBC and its a freebie (old episodes of the original Brit version of The Office.)

Bottom line BBC SW stopped in North America about a year ago. In Africa and South America they still transmit so some times you can get those.

Really the internet is the reason for the demise of SW. You don't need a radio to listen to radio if you have the internet.

One example was Radio New Zealand which is over 8,000 miles from the east coast of USA, my location. Late one night I heard a faint station in english. WIth my "guide" I guessed at what the station was. Getting on the internet I confirmed the broadcast with their internet simulcast. It's hard to get a 100% ID on stations some times, even with a guide.

Any way that is the night I realized I did not need the radio. Still I was pleased with the ability to get a S-5 with good intelligibility on a station so far a way. That still fascinates like it did when I was a kid 30 years ago. I use that station as a good measure of current conditions. Most of the time I am down in the S-2 but audible. It's not something you can really enjoy. They play very interesting music, old like Frank Sinatra and snips of old (30's, 40's. 50's) Brit radio dramas. The news is also interesting. I find it fascinating to hear what they listen to and actually enjoy it. But if I want to listen to relax I would go to the computer before the radio.

SW will never die but if your REALLY have to hear a show (not all scratchy) the internet is awesome. You can also down load programing onto you iPod and listen to it any time walking, working, driving..... Of course not every one has access to high speed internet.

Satellite radio is limited and also cost a monthly fee.....that will take more time to catch on and the satellites I think are only over North America.

DRM is pretty good and I get Canada 800 miles away and the quality is like local FM. Not sure its great for super high fidelity music but for voice and some music it is great. That

might save SW but than you need a DRM radio or a radio, 'I-F' converter and computer to run DRM decoder.

5949. Antenna the second

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-11-22 02:38:26 UTC
From: dean_0_way
Topic: 5949 Message: 5949

On a lark ? i hooked my rain gutter (center of a 45 foot run)to my portable radio last night and ran a wire to earth ground.

Not a big help but got some gain ,mostly noise ,and big overload on my local :) then i began thinking that earth ground may be giving the noise so i pulled that, which left only one wire attached to the set , seemed to be much better but during the day the radio was dead , so experiment # 2 ?

Put a solid (not stranded) single wire around a double window and hooked both wires to am clips on set, no earth ground. Fed by a piece of shielded microphone wire ,not much gain but very quiet. Daytime will test further .

Now the question is , would i benefit from a tuning cap on this single wire loop? it's about 6 wide by 4 feet tall . Iv'e been looking all over online, and cant seem to make up my mind if it's worth the trouble ? Or would more turns give more gain?

Thanks in advance !

Even though you may have less signal strength indicated with a loop
antenna, you will also have much less noise, so that signal-to-noise is
increased.

> Now the question is , would i benefit from a tuning cap on this
> single wire loop? it's about 6 wide by 4 feet tall . Iv'e been
> looking all over online, and cant seem to make up my mind if it's
> worth the trouble ? Or would more turns give more gain?

Yes. A single turn loop will get you up into the SW bands. Varying
the size of the loop and/or capacitor will affect exactly where in the
SW bands. Use a standard 9.6-365 pf (or 380 pf) capacitor. There are
a number of sources. MTM Scientific, Crystal Radio Supply, others.

http://www.mtmscientific.com/

http://www.crystalradiosupply.com/

http://www.midnightscience.com/catalog5.html

Here's a calculator that works well:

http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

With a 9.6-365 pf cap, and 15 turns around a square 17" x 17" form (24"
diagonal) 1/8" spacing, you will tune the AM/MW broadcast band.

With one turn approximately 30" x 30", you can tune from the 60 meters
band up to about 15 meters.

A polyvaricon dual 266pf cap with mating shaft and knob can be found at
http://www.angelfire.com/electronic2/index1/index.html That would give you
520pF.
It's unlikely you'll find an exact 400pF cap; 365pF was the standard for
radios. Lots of places sell those; some sell the dual-365pF version
too--that would work too but would be overkill. Probably the loop will tune
properly with a standard 365pF cap.
This is one place that sells the old-style 365pF caps.

THANK You Paul ;

So here is what the handy calculator says?

A loop of 4 windings
75 ''wide ,63 ''high
spaced 0.25 ''
with 365-9.6 cap
tunes from .7477 to 4.610 Mhz.
Almost the middle of AM ,up to 5 meters?

Now i thought ,what if i use a double cap of 365-9.6 and add a
ceramic cap of about 50 pF in series we get ;
780 max 69.2 min cap
That get's .511 to 1.717 Mhz ? much closer to the AM band ,Oh !
did i forget to mention this is for just AM ? , i'll build a
Shortwave project later .

What i need to ask ?,am i on the right track Here?

Can we just addd capacitance this way or does that defy logic?

Thanks

From: Hue Miller
Topic: 5957 Message: 5957

At least in the USA, BBC radio is carried at night on many
Public Radio, FM stations. SW broadcasting and indeed
SW use in general has been in steady decline for many
years. It amuses me to see the short-lived campaigns to
complain and try to reverse such decisions, after the latest
broadcaster drops HF. There really is little point in running
an expensive HF broadcast operation for the sake of a
small audience, and that mostly hobbyists, and hobbyists
being of a mostly certain age range and gender.
I sometimes wonder why some stations are still on the air,
and who exactly the target audience is. For example, the
high power Brasil station on 11770 or thereabout. (Altho
i love to hear the Vallenato or Llanera music from that area.)
I think maybe the HF broadcast spectrum may eventually
be repopulated to some degree with smaller, private
broadcasters more like "hobby broadcasters" than the
classic big national operations. Perhaps that would look more
like the early days of HF broadcasting, in the mid-1930s.

Dean-o,

Yep, you can alter the resonant frequency of a tuned loop by adding or subtracting capacitance. Eventually, however, you fall victim to the law of diminishing returns.

Large value variable capacitors are rare and expensive.

You can switch in fixed capacitors but, as the total capacitance is C(variable) + C(fixed), your capacitance ratio changes. A 10-100pf variable on its own has a capacitance ratio of 10:1. If you parallel up a (say) 100pf fixed, the combination now has a variable of 110-200 pf which is less than 2:1. This means that although the bottom tunable frequency is now lower, the range of frequencies which can be tuned has reduced. The mathematics of the tuned frequency has a frequency change relative to the square root of the capacitance values. A ten to one capacitance change will produce a frequency change of (SQRT 10) or 3.3. A two to one capacitance change will produce a frequency change of about 1.4.

That's not all that will bite you. The wavelength of the signals to be tuned also comes into play. The gain (or receivability) of the loop varies with the relative physical size of the loop and the wavelength of the tuned frequency. The larger the loop is relative to the wavelength of the signal, the more native gain the loop will have and so the bigger IS better rule applies. When you tune a loop down by adding capacitance, the size of the loop does not change and the loop "appears" smaller to the new bottom frequency and so loop relative gain drops.

The best solution to lowering a tuned band is to increase the size of the loop. If you can't physically make the loop any bigger, increase the number of turns. However, once you start increasing turns, the gain of the loop starts going down relative to a bigger loop.

In your case where you are not altering the bottom frequency too much adding variable and series capacitance to set your band limits would not affect the gain too much.

Your logic is up to the mark:- It is common practice in tuners to align the tuning capacitors by the addition of "padder" and/or "trimmer" capacitors. If you look at the plastic encapsulated tuning capacitors of small transistor radios, you may see openings with a screwdriver slot beneath: these are built-in alignment capacitors. Anyone thinking of improving the performance of their radio by fiddling with these settings - DON'T. They are factory set and need an educated hand and test equipment.

I have a problem with your maths however. Two 365-9.6pf variable capacitors in parallel produce a 730-19.2pf capacitor. If you add a series 50pf - values go to 46.8-13.9pf. I think you meant to add your 50pf in parallel. This will give 780-69.2.

Dean-o, you are obviously a thinker - go for your Ham licence; you will learn a lot.

Deano, actual experience would say that 511 khz - 1717 khz is cutting it far too close. Up on the top end the frequencies are very close together with 850 khz being in about the middle of the capacitor range.

And there is just no need for a loop that large.

Another consideration, loops are highly directional, which is good for pulling that weak signal out of the ether, or better, nulling that noise souce, whether a strong station or noise producer in your home.

The very large loop you want to make, around the window, will not be easily rotated. Also, there seems to be diminishing return with increased size, that is, a 4' box loop does not give much better performance than a 2' loop.

Using that same 9.6-365 pf capacitor, winding 15 turns of 22 ga wire, with 1/8" spacing between windings around a 17" x 17" form gives good range from just below the AM Broadcast Band to just above. It will be easy to rotate. I place the loop on an old "Lazy Susan" with the radio (Grundig S350DL) next to it, and it picks up by mutual coupling. I can orient the radio and antenna for good coupling, and then rotate them together. This is for radios with built in ferrite loopsticks.

But for radios with no internal antenna, such as my Icom R75, you will need a coupling loop of some sort. This can be done two ways.

You can add an extra turn of wire to the loop form, not connected to the main windings (which attach to the capacitor). This extra turn is a "sense winding" or "pickup loop", and the two ends connect to your radio's Antenna and Ground terminals.

I have also formed a small loop from RG-58 coax, by trimming back and exposing the center conductor on the end, forming the end of the coax into a one turn loop about 1' diameterand soldering that center conductor back to the shield. Then I put a PL-259 on the other end of the coax and screwed that to my R75 receiver.

This pickup loop is attached to the side of the tuned loop. And this works very well, too.

You can buy the plans and tuning capacitor from MTM Scientific. There are photos here in the Photo section in a folder called Loop Kits. Also MTM's links are posted in the Links section. If you go to MTM's AM loop link you will find photos of an added pickup loop, and a link to my antenna.

Paul

This is correct ... as far as i am concerned being able to tune the whole frequency range with one set of values for the loop and the capacitor is only academic. I recommend keeping the tuning range to the first half of the capacitor rotation. Adjust the loop inductance so the bottom of the desired range coincides with maximum capacitance. I generally divide the mw band I construct loop for 300 to 600khz or 540 to 1000khz. I don't do a lot of dxing beyond 1000khz.

>And there is just no need for a loop that large.

I agree with this statement. Once you get beyond a 2' dimensioned loop performance meets a rapidly diminishing return in performance. Again we are talking about a tuned loop for MW reception. The signals on the mw band are generally strong enough and do not require added loop 'capture area' .... unless you are a purist using a crystal set receiver. What you want is a very HiQ antenna with sharp nulls that can deal with the main problem of a multitude of stations ... many on the same frequency!

>Another consideration, loops are highly directional, which is good
>for pulling that weak signal out of the ether, or better, nulling
>that noise souce, whether a strong station or noise producer in your
>home.

Yes and no. I find the reception nodes of the pattern are quite broad ... however the null portion of the pattern is quite sharp. In other words, one of the main benefits of the HiQ tuned loop is its sharp null. Rotating angle and azimuth can be used to separate stations on the same frequency by nulling out one or the other.

>The very large loop you want to make, around the window, will not be
>easily rotated. Also, there seems to be diminishing return with
>increased size, that is, a 4' box loop does not give much better
>performance than a 2' loop.

As mentioned above, one of the main benefits of a mw tuned loop is the ability to physically manipulate it. there is little if any benefit from a large fixed tuned loop. A well constructed 2' to 3' tuned loop is about the maximum practical size. A 1' circular tuned loop can produce amazing performance. Building a good mw tuned loop is as much a matter of good physical construction as electrical. Even the electrical part depends on

the physical qualities of the components. Performance (maximum) will depend on the kind of wire and method of winding .... as well as the quality of the capacitors used for tuning. Capacitors (maximum performance) will have very low dielectric loss and have smooth movement.

There is argument about winding technique as well ... some like the spider technique and others like the more traditional frame type winding. I personally find the standard solenoid form superior as far as Q and narrowness of the null. A lot of the construction is aesthetically driven hihi

Hi Lee,

I just put the title of this posting into the eBay search box and it
came up with quite a few hits.

If your like me you may prefer to restrict your search to "UK only" to
avoid all those possible complications with import duty etc.

Try cut-n-pasting the following link into your browser (Without the
enclosing brakets) if the link fails then try putting "Vacuum Variable
Capacitor" into the eBay search box and then refine your search to "UK
only" if you prefer.

(http://shop.ebay.co.uk/items/__Vacuum-Variable-Capacitor_W0QQLHQ5fPrefLocZ1QQ_dmptZUKQ5fC
onsumerElectronicsQ5fSpecialistRadioEquipmentQ5fSMQQ_flnZ1QQ_trksidZp3286Q2ec0Q2em283)

The prices looked pretty good, not as cheap as bring-and-buy rally
prices a few years ago but very mmuch in-line with what you might
expect to pay.

I hope this helps.

Hi Lee,

I just put "Vacuum Variable Capacitor" in the eBay search box and it
came up with 12 hits 10 of which are UK sellers. Various values of
capacitance/working Voltage and at prices that seem quite reasonable
for new components.

Hope this helps.

Hue,
I agree that there is very little HF in the US, but I've been involved for more than 20 years in installing high power broadcast sites throughout the world, and in much of the rest of the world it is alive and well. The installations now are all going forward with transmitters and exciters that can broadcast in AM or DRM. DRM is a digital broadcast mode with almost CD quality, and although the receivers are rare right now, the broadcasters are putting quite a few broadcasts on in digital mode. CBC has broadcasts throughout the day from Sackville Canada. I've even listened for hours to digital broadcast from New Zealand. I received a nice QSL card from them when I sent a signal report. For a receiver, you can modify a standard HF receiver by bringing out the IF to a simple down-converter, and feed it into a computer sound card. "DREAM" software is free and will convert the signal to audio. So new things are happening on HF.

I know it's not a pure loop antenna thing to post, but it works very well!

Last night I listened to Radio Havana and Radio Iceland on this. Radio Havana came in blasting, I had to keep the headphones off my ears. Selectivity was very good, I could pick out Radio Iceland's signal very well!

Today I added the shield over the variocoupler and a second variable capacitor to aid in regeneration control.

Tube lineup=Cossor brand valves, from left to right: 215SG (tuned Tetrode RF preamp), 210HL (regen detector), 210HF (audio gain).

Great discussion !

Maybe i should lay out my purpose for this loop,

Prob 1
I live in a stucco house ,so it has that lovely steel mesh skin under the stucco ,While it's nice to look at ? and low maintainance ,it's a signal killer.

Prob 2
Also have a 5000 watt local 2 blocks away

I wanted somthing a little stealthy ? well at least not so visable. To get max signal it was going to have to be outside the house . Easy to build .

Even though it's going to be 90 Degrees off what i actually wanted and it may be oversized ? i think i'll go ahead and put it together , i've learned a lot just from building 2 small loops and from what iv'e been able to figure out on this one ,I think it's worth a try to complete it .Besides if actually learn more by failing than success?

I was concerned about how tight i had the tuning range as well ,so i think i'm going to just hook the variable cap on it at first , then add the extra cap only if i need it ? that brings the top freg. higher but ,o well it's another experiment i can try ?

Iv'e seen some 4 foot loops on the net ,they seem to work ok? this one is roughly 4 times that size ,lol , can you say overkill?

I did notice that the calculater seems to change a lot according to how close the wraps are wound , seems strange to me , i remember reading somewhere that it should'nt make to much difference , but then some say it's very important ? i'm thinking of using one width wire of space between wraps, i can change that later if i need too ?

Anyway the test continues ,I'm having fun ,and nobody gets hurt ? Thanks for the tips !

Hi,

Looking at ur pictures brought back old memories .... especially the
filament adjustment .... when I was a kid I saved up to buy my first tube
(valve) #30 as I recall ... a triode with a 1.5v filament ... the first
time I fired up my receiver the filament lit up and burned out!! I never
forget that and always took extra care with filament voltages after that hi hi.

Your project looks like a lot of fun.

Jim

Thanks Des, quite a collection at very reasonable prices..

I have already searched fleabay and am looking for a supplier who i can collect from which gives me a chance to view before purchase and also validates the vendor ... (I have had a bad experience with fleabay) ... and is a lot cheaper to collect .. obviously close to Birmingham of course .... I would even purchase privately. ;o)

I had an email from someone on here asking why i wanted a vacuum varicap just to receive!! - who said i wanted to just receive on a magloop ??? all I can say to that person is :- the clue is in the callsign!!!

Cheers.

Hi Lee
A local ham is selling a couple. Don't know how much post is to the UK
but might be worth looking at:

http://www.vkclassifieds.vkham.com/cgi-bin/classifieds/classifieds.cgi?session_key=&search_and_display_db_button=on&db_id=59023&query=retrieval

I have a metal shop building out back, and my loop works in there. I have a friend with his ham shack in his basement, and his loop works down there. At the very worst, you may have to place your loop near a window, but I think you will be surprised at how well it works.

Adding a fixed cap in parallel with the variable cap will narrow the tuning range. It is better to adjust the number of turns in the loop, or if a single turn loop, adjust the size of the loop.

There is capacitance between the turns of wire. That is why the
spacing makes a difference.

Deano-o; I'll second Jim & Paul. I've got the MTM almost 2ft dia loop. I built a 3.5 ft effective diameter loop. The size (volume) difference of two antennas is amazing and 3.5 footer is gangly for indoors. Size aside, the performance difference was not worth mentioning. I'm sure in the desert, 1000's of miles from man-made noise, the 3.5 footer would rule. But in my urban environment I did not get louder, clearer DX signals, I got louder DX signals with correspondingly louder noise. I concluded I'd maxxed out w/ the 2ft loop. I use the loop indoors only btw. You want to mount outdoors? Then you will need to use a variac or some such for remote tuning.

I've gone "one better" than the MTM loop however. I stumbled upon a very hot setup where the sum is greater than the individual components. I use a CCrane Twin-Coil direct-connected to a given radio. I then place the 2ft loop very close and in differing approximations to the T-F ferrite head. The two antennas magnetically couple. When I peak them both, I have as good as, maybe slightly better selectivity (Q seems to improve slightly). With both antennas working as resonant circuits, not much but the exact frequency you want gets through so problems from the locals are a thing of the past. I get better s/n. Yes, better s/n, not just signal strength. And I get interesting and powerful nulling abilities. Best example is I'm in Milwaukee. I've got two stations on 580 - one in Urbana, Ill, the other in Traverse City, MI. They are about 35 degrees from one another and I can null either one 100% during daytime using the two antennas. Can't quite do that with either antenna alone.

Closing thought: If I had to choose between a 2 ft loop or the T-F, I'd choose the loop.

Like you say, have fun!

-Mark

PS - I picked up some Litz wire. Am going to downsize the old 3.5 ft frame PVC frame to maybe 2.5 ft effective diameter and see what happens.

Oh man!
It's like you read my mind?
Iv'e been holding off the itch to buy one of those twin coil ferrite
jobs for about a month ,and you go scratch that spot again ? he heh,

Actually i was going to use this new loop in tandom with a twin
ferrite ,if i ever get one !

Where is that credit card now.....?

Hi Mark,

well you have stumbled on one of the tricks of the crystal set dx crowd ..... using 2 or more loops (inductors) ... to increase gain and/or to provide added selectivity/rejection. With the xtal set crowd rejecting a strong adjacent signal is often the problem ... set one loop for maximum gain on the desired frequency and then set a second loop to the station on the adjacent frequency. then orient the loops one to the other and the second loop will literally 'suck out' the adjacent frequency allowing reception of the desired station. Sometimes 3 and 4 tuned circuits (mini loops) can be used.

If you are doing very weak signal daytime reception the first loop can act as a kind of antenna tuner if you have a long wire antenna ... couple the tuner loop to a second loop and then to the receiver. You can copy stations you couldn't even hear with the best stand alone mw receivers like a Superadio.

Yaa i was thinking that myself HOWEVER !.........Iv'e been trying to
find a GOOD deal? ,on a pana 2200 or a Zenith trans -o for about a year
Cant see all the hub-bub about the economy bieng so bad ? ,when most
will bring close to new price? And those Sony 2010's ? Yikes!
I even saw somebody buy a broken T-O for almost 200 bucks heh!
So far the Ferrite 's have been getting to within 10 dollars of new
price so I'm still lookin?
The off brand stuff is getting cheap though! i got a LLoyds ,a
Panasonic 5000 look-a like ,for 40 d's ,waiting for it to arrive .

Dean_0

Cheap'os are the best'os?

Wow. I just saw a dusty Panasonic 5000 go for $36, so it can happen.
The thing w/ eBay I have noticed ... it's like going into K-Mart
hoping you got there just in time for the blue light special.
Sometimes you get lucky, sometimes not. But keep your eyes open ... I
grabbed my T-F for abt. $60 like new off eBay. And that was when the
economy was good.

Hi,
I remember seeing pictures of similar set-up's in old pre WW2 battery domestic radios,
A large diameter vertical coil with a smaller rotatable coil within it, the position of the smaller
one being controlled by a shaft through the wall of the large coil.
Could this be a tuning system of some type ????

Exactly!!
the inner coil is tuned by rotating the shaft, it lessens the coupling, usually to the antenna. Loud signals will overload the detector on these older sets, so 'de-coupling' both decreases sensitivity and increases selectivity. This is a common component on the old regenerative receivers back in the 20's & 30's.

I've got one of these gadgets. Picked it up last year at a hamfest
for a few dollars.

It's an antenna coupler, with a manual control that turns the inner
coil 90 degrees, such that at one extreme the two coils are fully
concentric and coupled, at the other extreme the inner coil is
perpendicular to the outer (and thus "decoupled"). I guess the
coupling is a kind of gain control. There's no tuning or changing of
inductance involved here, just changing the amount of inductive
coupling between the inner and outer coils.

The outer coil has two windings, side by side, about 10 turns on the
smaller winding and maybe 25 or so on the bigger winding. The inner
coil has maybe 20 or so turns on it.

Mine is very old (pre WWII I think), using bakelite and green-cloth
Litz wire, with nice nickle-plated screw-down connectors to all the
coils. Looks like it might have been part of some old lab equipment,
or possibly an old AM radio.

I've never used mine, but I'm going to hold on to it and one of these
days try it out on AM broadcast signals or 160M.

Someone else here had identified that device as a "variometer". That term is used to denote an avionic device something quite different from what's under discussion here], but here's the relevant explanation: http://www.qsl.net/in3otd/variodes.html

Adjusting the mutual induction [from "add" to zero, and then to "buck"] by rotating the inner coil is how it works. Probably, the distributed capacitance provides the necessary capacitance to constitute a tuned circuit. The calculations are waaaay beyond me, but I'm "guessing" that the tuning range would be sufficient for the purpose. Litz wire, and NO capacitor, sounds intriguing!

> for a few dollars.

I just uploaded a picture of my "variometer" in the AF4EX.RADIO files.

As you can see it has a wooden base and a nice big knob. The coil is angled 45 degrees from the axis of rotation so that you have to turn the knob 180 degrees to move the coil through 90 degrees. Looks like it might have been used for teaching or experimentation.

The guy I bought it from (at the Melbourne Fl hamfest) knew nothing about it and thought it was just useless junk. I think I gave him $3 for it!
:-)

In avionics a variometer measures changes in altitude but we are talking
about wireless not aircraft.

Hello Everbody,
I'm new to the group,but not new to swling. I'm looking to get a new antenna.At the present time, I'm using a 15 ft. piece of #14 insulated wire draped over my bedroom window hooked to a Grove Mini-Tuner to my receiver(Yaesu FT-747GX). Reception isn't to bad, but could be better. Grove has a Flex-Tenna (24ft long) that can be put either in the atic or run around the ceiling.
Has anybody used one of these or know antbody that has?
Any comments---YAE OR NAE

Thanks,Mike

That looks pretty sturdy, Mike. (Don't think mine would take more than a watt or two without burning up).

My initial impression was that a variometer could be used only for coupling, but you say you're tuning your 600M antenna with yours. I guess if you connect the inner coil to one of the outer coils in series, then the total inductance of the series would indeed change. Is that what you're doing?

Would I be able to hear your station down here in central Florida? Are there any 600 meter operators in this area?

I've been experimenting with VLF lately down around 10kHz, receive only of course. Lots of natural signals to listen to. I've got a couple of hula-hoop (80cm) antennas with 40 turns of wire for wide-band VLF monitoring. I could easily resonate them at 600 meters. Would an opamp circuit and sound-card work OK as a receiver for your CW signals?

Tnx,
John/AF4EX

Bob,
I followed the link to Dave Schmarder's web site. The crystal radio variometer schematic looked simple so I built it on a little board and hooked it up to the antique variometer and my 80m dipole. The first signal that I heard stunned me: AM morse, a beacon sending the call letters "SQT", then I heard the Catholic global shortwave radio station and another faint station.

Does anyone know what and where the SQT beacon is?

The variometer was hooked up as shown in Scharder's schematic, the inner coil in series with the larger outer coil and the other outer coil attached to the dipole.

I posted a picture of this rig in the Files section under AF4EX.RADIO.

There is some tuning action as well as coupling from the variometer, but it's not as sharp as using the variable capacitor. I'd say it's mostly effective for coupling. But perhaps I don't have it set up optimally.

This is a lot of fun. I'm using the same "Trimm Dependable" high impedance (2Kohm) headset that my dad bought for me to use with crystal sets when I was a kid in the 1950's. Had to replace the original cloth-covered wire leads years ago, but the phones are just as sensitive as ever.

Tnx,
John/AF4EX

Hi John,

Beacon SQT is in Melbourne, Florida. 257 kHz carrier, tones +-1040 Hz.
It has been heard out here on the west coast, but not by me!

I live in Palm Bay, adjacent to Melbourne, so the transmitter's
probably not too far here if I can hear it up in the shortwave bands,
on a crytal radio set!

Thanks for solving the mystery!

Thanks,
I found another navaid beacon list
http://www.airnav.com/cgi-bin/navaid-info
which gives the exact location of beacon "SQT":
Lat 28.0994689/Lon -80.7008083.
This happens to be 4 miles due North of my QTH (EL98PA). You can see
the antenna if you use Google Earth.

John
The variometer is a form of loose coupling. You will find a number of variations on the Crystal Radio sites. They are also used in VLF transmitters as someone has already mentioned.

Well done on your experiments.

Well, this thread was started by Dean_o who was looking for some advice on buying an antique variometer on EBay. Glad he mentioned it here because it provided me the motive to check out mine (and relive some happy memories from boyhood).

My advice to Dean_o would be to buy some PVC tubing and make your own, which can be customized to whatever frequencies you're intertested in.

I'm thinking of adapting my VLF hula-hoops into a variometer design to make it possible to resonate and tune them to the various Navy nav transmitters that operate between 10kHz and 40kHz.

HTH,
John/AF4EX

You must know by now i like the slightly wierd, or old mechanical
stuff the best?
These looked very interesting to me, so i thought ? give the loop
list something to talk about as well, I am sure going to check out
some possibilities for making one of these fit into my collection of
stuff!
To bad i got home a little late tonight and missed them both ,but
i'm sure they will have more a bit later ? or as you said , i bet i
can make one too!

Thanks All

Hi John,

The variometer is in the middle of the loading coil windings. It works excellent tuning my 70' inverted L vertical. I get coverage of the lower 48 states with just 90w output with regular CW. Have a look at www.500kc.com for more info on the operations. You should hear many stations where you live. Pat /6 is 4 blocks from the Gulf in Mississippi so it'll be a saltwater path between you guys. If you look at the station map on that site you can see where I am at. I am station #16.

I have connected the mic input on a soundcard to a 1:1 transformer connected to a feedline/wire antenna dn seen many signals in the VLF band. SAQ is one of them I have seen here but not very often. Lots of signals to listen and watch for in ARGO, Spectran or whatever is your favorite graphical software. Fun stuff.

HI to the Group .Thanks for letting me join

I want to put up a multi band 80 Meter loop fed with 300 ohm Window ladder line into a proper Balanced Tuner !,UP about 30 feet

Where the loop would be placed in the yard I have a 65 foot free standing tower with a 80Meter inverted V.

The tower will end up smack in the center of the Loop! Will this have any bad effect's on the loop ??

The Shack would be under one corner of the loop ! What would be the minimum lenth of the fed line??

Thanks TO ALL

Mark VK2FTMB

Hi Jim,

a long wire antenna is not as simple as many people think. Google "Beverage", "terminated long wire", "windom" and "OCF" antennas. You will find that the length, orientation and feedpoint of long wire antennas can affect how they work.

Having said that, a multiple wavelength long wire antenna can have excellent performance. And it does not have to be high. All you need is a BIG piece of land.

If you don't have a large chunk of real estate, then try a horizontal loop. While it may not have the performance of a multiple wavelength of wire, it does offer good receive performance and low noise at quite modest heights. But, if you want to transmit long distances, it really needs to be over half a wavelength in height.

You've indicated that you have 20-30 inches available. I am sure you mean 20-30 feet. Can you please confirm the space available?

If you come back with your location, your location(s) of interest, receive only or transmit, the space available and the frequency(ies) of interest, I am sure members of this group will offer you more detailed advice.

Ray,
vk5ugs

Jim,
You need to tell us what you mean by 'I can 20-30" either way'.

As far as orientation goes, it depends entirely what signals you're interested in: local rag chews, USA contacts or DX. Then orient the antenna with its major lobes pointing horizontally in the directions of interest. High vertical angle lobes for local stuff or low vertical angle lobes for DX.

You probably know that a half-wave antenna has its major lobes "broad side" to the antenna. A long wire has more wavelength multiples than a half-wave, and as the number of multiples go up the lobes tend to steer themselves towards the ends of the ends of the antenna ("end-fire") and the broad-side lobe diminishes (but doesn't entirely go away).

I remember setting up a long-wire antenna in the Philippines on top the dormitory building where I stayed (many years ago). Worked like gangbusters on 20m, getting my 100-watt signal into the US, both coasts.

HTH,
John/AF4EX

Dear David

thanks for the video

very nice implementation

I am wondering about the placement of the termination resistor (variable, nice) and the balun at the bottom corners. I thought usually the flag is constructed with these at centre height on the vertical portions of the antenna. Do you gain an advantage in the gain pattern at the bottom or was (and is I should say) just convenient to put them at the corners

best wishes
Paul in Guelph ON Canada

I have a very old variable coupler that I was told by the
man who had it that he used it for a crystal radio before
he had a variable capacitor, it allowed him to tune stations.

I have a picture to post but have not yet worked out how
to do it, I am into the forum but can't seem to get it on.

I first saw this unit on the friends bench in the early
fifties. When Myron died his son gave it to me, I'm
70 and the son just passed away at age 84 so the unit is OLD.

I have a couple oddities that I was given at the same time,
I'll have to photo and post them.

> Am interested in comments.

Looks old Herb. Very old. I think you have just won the "Oldest Variometer" contest! :-)

I'm assuming the rod on the side spins the rotor coil inside the stationary coil, which appears to have two windings (in the circular opening), which would make it functionally similar to the one I have.

Have you tried it out?

John/AF4EX

Herb,
http://crystalradio.org/May98.html
I found this group called the "Xtal Set Society" which published a
picture of a 1922-vintage variometer in their May-98 newsletter.
It's round, not square, but otherwise looks a lot like yours.

Perhaps yours is even older.

You might want to contact them and show them your photo. They can
probably pinpoint the era it was made.

HTH,
John/AF4EX

I completed an evaluation of bipolar transistors that are suitable for
active antennas and preamplifiers and placed the results on my web page at:

http://www.home.earthlink.net/~christrask/Paper015.html

I hope to live long enough to see this trend of using obsolete
transistors in new designs come to an end.

6033. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-12-02 00:12:47 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6033

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

Put a stub in the reflector near a corner and tune it to about 5% lower in frequency than the driven element after you have it tuned.

Jim, do a google search for Select-A-Tenna I see one on Amazon.com but
it's $99.00 which I think is ridiculous.
I think I paid about $12.00 for mine used.
I also see a Terk Technology version from $28.29.

My select-a-tenna works very well with an ordinary AB broadcast receiver
. When I tried it with my SuperRadio III it didn't help much as the
radio has an rf amp and doesn't need the help.
There is also a powered Super Select-A-Tenna but it costs $199.95 new.
Should work quite well but I've never tried it.
Lots more hits on that search. Good luck. 73 Gary N9ZSV

Hi,

You could build your own ... such a form could be made from a crochet hoop which come in various sizes and can be found in craft stores. However, I believe the Kenwood R1000 does not have a ferrite tuned antenna and would not work with just close proximity to the loop. You would have to include a second pickup loop on the form. Some of the commercial models include this feature and some do not.

Jim

I have a Kenwood R-1000
In hooking up antenna I found 4 places in back of radio in a row
from left to right
Red MWANT Black GND Red SWb SWa(male plug)
below all that is a SW ANT select switch
which switch from SWa to SWb.
I think I know what the a/b switch is for
and I understand the Black is as well as the SWa (male)
But I don't know how to connect the 2 Red they are 1/2 X3/8 "
squares?

They are for a non coax antenna leadin like ladder line or just a wire.
Usually the impedance will be more than 50 ohms.

Hello every one.

I'm a new licensed amateur of The Netherlands just got my call in October :) Was always intrested in amateur radio since a small child. Have a ts-520 for hf and a ts-700 for 2 meters. Been reading the news letter for a while though.

My questions is as follows:

1. I have a restriction in placeing an antenne, and wonderd if a 2m loop antenne will help in covering most of the reapeters close to me? I do have a small mobile antenne to use for genreal coverage but can only connect to 1 repeater at the moment, that is why the question.

2. If I make a magnetic loop antenne for 2m what is the gamma matsh for that loop? I know if I make a 30cm diameter loop the Ferreday loop wil be about 6cm, but what must the gamma matsh be for the 2m loop?

3. What is the best diameter for a 2m magnetic loop?

4. Where can I get information on Gamma Matsh for Magnetic Loop antenne's?

5. What is better the Gamma Matsh or the Ferreday Loop?

Gr Paul M Tas (PD0TAS .--. -.. ----- - .- ...)

Yes, a full size (1 wavelength) loop on 2 meters is a very good antenna ... far superior to a small mobile antenna (I assume you mean like a rubber duckie). However, you might consider making 2 loops .... one a driven element and the other a parasitic reflector or director ... a cubical quad ... which has further gain over a portable antenna and directional qualities.

>2. If I make a magnetic loop antenne for 2m what is the gamma matsh for
>that loop? I know if I make a 30cm diameter loop the Ferreday loop wil be
>about 6cm, but what must the gamma matsh be for the 2m loop?

Maybe I am missing something here. A square loop (easiest to construct) would be approximately 7 ft or 2.5 mtrs in circumference. About 1.75 ft or 53 cm to a side. This would be a full size 1 wavelength loop. Such a loop is self resonant at 2m frequency. It can be constructed of wire ... supported by a plastic frame or copper tubing that is self supporting. The usual method of coupling to a coax feed line is to use a gamma match not a faraday loop.

A small tuned loop (usually defined as 1/10 of a wavelength in circumference) is often coupled using a faraday loop nominally 1/5 the circumference of the main loop. However, a loop 53 cm on a side may look small but is in fact full size at 2m frequency.

There are many articles on the internet giving complete instructions on constructing such a loop for the 2mtr band.

Again I make assumptions that you are making a full size loop for 2m band .... not a portable antenna. I have used such an antenna and it is very efficient. It takes little additional effort to construct a second similar parasitic element giving additional gain and directivity. Heavy wire works well at low power.

I think this answers your other questions as well. Search the Internet for 2mtr loop antennas and you will find a number of full construction articles.

Jim hr again.

If you search the internet some of the best articles are found under '2mtr cubical quad'. If you just want a single loop then just leave the second element off hi hi.

Hello Jim

My problem here is I don't have space to do a number of quad's. I have to make it so that only one loop can work in my situation. I have to make it so that I can turn it on a pvc pipe so that its easy to turn around and easy to tune the cap. So a quad is out of the question for me like you said a director and reflector I can't use at this stages. I looked around for a 2m magnetic loop and found one and made out of -+ 3mm wire/rod and the curcramfrince is about 54cm so its not that big and I can use it in my home/flat. Will keep you all up to date. Only now I need to find a 0.. to 20 pf cap.

Yes, a full size (1 wavelength) loop on 2 meters is a very good antenna .. far superior to a small mobile antenna (I assume you mean like a rubber duckie). However, you might consider making 2 loops .... one a driven element and the other a parasitic reflector or director ... a cubical quad .. which has further gain over a portable antenna and directional qualities.

>2. If I make a magnetic loop antenne for 2m what is the gamma matsh for
>that loop? I know if I make a 30cm diameter loop the Ferreday loop wil be
>about 6cm, but what must the gamma matsh be for the 2m loop?

What I ment was that what is the length of the gamma matsh when you build a loop. Thing is I know what the curcramfrince is of the matshing loop is 1/5 of the big loop but what is the length of the gamma matsh???????

Maybe I am missing something here. A square loop (easiest to construct) would be approximately 7 ft or 2.5 mtrs in circumference. About 1.75 ft or 53 cm to a side. This would be a full size 1 wavelength loop. Such a loop is self resonant at 2m frequency. It can be constructed of wire ... supported by a plastic frame or copper tubing that is self supporting. The usual method of coupling to a coax feed line is to use a gamma match not a faraday loop.

A small tuned loop (usually defined as 1/10 of a wavelength in circumference) is often coupled using a faraday loop nominally 1/5 the circumference of the main loop. However, a loop 53 cm on a side may look small but is in fact full size at 2m frequency.

There are many articles on the internet giving complete instructions on constructing such a loop for the 2mtr band.

Again I make assumptions that you are making a full size loop for 2m band ... not a portable antenna. I have used such an antenna and it is very efficient. It takes little additional effort to construct a second similar parasitic element giving additional gain and directivity. Heavy wire works well at low power.

I think this answers your other questions as well. Search the Internet for
2mtr loop antennas and you will find a number of full construction articles.

I've been using a 2m J-pole with good success. It is on the top of a 20' (6m) mast, and I easily hit a repeater 45 miles (72 km) away with only 8 watts.

Yeh, I started receiving Grouply invitations this year. No idea on which Yahoo group it might have started since I'm on several, all radio related. No biggie, I just delete 'em and block the sender. Some folks who tried Grouply didn't realize that what they considered personal information such as mailing lists might be hijacked for spamming by Grouply.

I almost agree with you.

However, there's a couple of members on another ham radio oriented group I belong to, who wisely use Grouply, and I and the group have never seen any spam or other junk from these folks. The only reason I know they use Grouply, is a 1-line mention of it at the bottom of their emails.

So it is possible to use Grouply and not have trouble. But you need to know to change the settings, to make Grouply behave.

(I am not in favor of indiscriminately banning anyone who uses Grouply. Only those whose use of it results in unwanted junk for the rest of us.)

Put a stub in the reflector near a corner and tune it to about 5% lower in frequency than the driven element after you have it tuned.

6070. Three question about Loop Antenna Construction - Wanting something for LF band.

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-12-07 21:49:16 UTC
From: sernstfortin
Topic: 6070 Message: 6070

Loop Antenna Calculator predicts the loop antenna I'm currently constructing will be put into resonance in the MW band, but I'd really like to tune it in the LF band.

Actually, I'd like something that tuned from 30KHz to 500KHz. I must be dreaming, right?

Three questions.
First: if I have a simple rectangular loop, and I'm constrained by how much wire I use and it's spacing, can I artifically add capacitance in parallel to the tuning capacitor, and inductance in series with the main resonant coil to shift the low- and high- tuning extents of the antenna, or am I just shooting myself in the foot?

Second (2 parts): most if not all the loop designs I've looked at use one coil for the pickup or sensing coil. Can I use multiple windings, and is there anything that says it can't be wound at the same extents of the main loop, or must it reside inside of the resonant main loop?

Third: do I need to use a pre-amp on the sensing loop brought back to the radio?

6071. ? inductance

Date: 2008-12-08 04:43:33 UTC
From: dean_0_way
Topic: 6071 Message: 6071

I'm using Bruce Carters formula calculator;
http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

My question is ? In making an air loop is the point to make the inductance as high as possible to have maximum gain ,or is there a limit to how much inductance you should try to get in the loop ?

Another Question i had is , is there a way to block a Freq. I have a AM station 2 blocks away, I thought if i could block that single Freq, it wouldn't overload my reciever ?

Thanks ,,

The range may be a little large .. You may need to do some switching of turns and/or capacitance.

>Three questions.
>First: if I have a simple rectangular loop, and I'm constrained by how
>much wire I use and it's spacing, can I artifically add capacitance in
>parallel to the tuning capacitor, and inductance in series with the
>main resonant coil to shift the low- and high- tuning extents of the
>antenna, or am I just shooting myself in the foot?

Not sure what you mean 'artificial' .... you certainly can connect 1, 2, or 3 capacitors in parallel to lower the range. You can also tap the loop to lower/raise inductance.

>Second (2 parts): most if not all the loop designs I've looked at use
>one coil for the pickup or sensing coil. Can I use multiple windings,
>and is there anything that says it can't be wound at the same extents
>of the main loop, or must it reside inside of the resonant main loop?

The pickup loop is usually 1 to 3 turns (untuned) in proximity to the tuned loop. The pickup loop is tricky ... in my experience the inductive coupling has great effect on the efficiency of the tuned loop. Too much coupling lowers the Q ... it is best if you can adjust coupling.

>Third: do I need to use a pre-amp on the sensing loop brought back to
>the radio?

A tuned loop usually provides sufficient signal for modern receivers .... in this case the coupling is adjusted for a compromise between maximum signal transfer and best loop selectivity (Q). If you are designing an untuned loop a pre-amplifier is usually necessary ... and is best located right at the feed point to the loop.

Jim

OK. I can add capacitance. What type of capacitor would be necessary? Non-polarized, non ceramic?

Can I add an inductor in series with the coil? ;)

You mentioned the sensing coil... If the loop is square, can the sensing coil be round? What else can you tell me based on your experiences?

Your responses have been very helpful, thank you.

It's a bit difficult to explain in text form. The inductance and resistance of the loop are not directly related, and the loop actually takes on the form of a shorted transmission line after a point, while the resiatance has it's own characteristics. The guiding quantity is the antenna efficiency, which happens to coincide at about the point where the inductance makes that transition, and before the resistance becomes asymptotic (sp?). I wrote about this in:

"Active Loop Aerials for HF Reception, Part 1: Practical
Loop Aerial Design," QEX, Jul/Aug 2003, pp. 35-42.

>

Yes, you can put a high-Q parallel-resonant trap in the feedline between the antenna and the receiver, if it's a single station. If it's multiple stations, then a sharp highpass filter would be a better option.

Chris,
Can you take a loop and treating it like an LC circuit in resonance, add some parallel capacitance via capacitor, and series inductance via inductors and shift things into the band you ideally want?

I got the makings of a decent AM/MW loop predicted by Carter's formula which I want to bring down to the LF band below 500KHz without doing too much to it.

And:
I have an RF signal generator.. Can I attach a small whip to it say, then attach the loop to my radio and check resonance / operation that way so I have an idea of how it'll work before sticking it outside?

It's getting cold down south.

Thanks,

>OK. I can add capacitance. What type of capacitor would be necessary?
>Non-polarized, non ceramic?

I have never used fixed value capacitors ..... You would use values with low dielectric loss ... perhaps others might suggest quality fixed value capacitor types. I have used multi unit capacitors ... eg. a capacitor with 2 or more gangs ... e.g. they might be 365 pfd per gang on the same shaft. You could use just one ... switch in a second ... switch in a third.

>Can I add an inductor in series with the coil? ;)

I suppose you could use a switched in series inductor .... although I have not done this. Switching in a series inductor would indeed increase the total inductance in the circuit allowing resonance at a lower frequency. As mentioned before, I have changed inductance by reducing the number of turns on the loop itself by shorting them out. This starts with maximum inductance and reduces inductance as turns are shorted out thus raising the resonant frequency.

>You mentioned the sensing coil... If the loop is square, can the
>sensing coil be round? What else can you tell me based on your
>experiences?

Yes, one loop doesn't exactly care what the shape of the other loop is hi hi ... but as i mentioned, the loops interact and the best performance is a balance. A Goldylocks situation ... not too much and not too little .... but just right. I have found it best if the pickup loop can be physically adjusted for best coupling. In order to achieve this requires that they are moveable in relation to each other. Maximum coupling occurs when the main and pickup loop are in the same plane. Thus, rotating the pickup loop in relation to the main loop will reduce coupling .... with minimum when they are 90 deg to each other. A mechanical problem hi hi.

You mentioned filtering out signals ... this is possible with dual loops .... one loop tuned to the desired frequency/station and the second loop tuned to the frequency of the offending station splashing over. Carefully move the loops together (until coupling is just right) and the second loop actually appears to 'suck out the offending signal). The second (sucking loop) does not have to be large ... but high Q.

I must mention that my tuned loop experimentation has been either for mw ... 540-1700 or SW in the 5-15 mhz range. All previous comments were related to MW tuned loops.

Tuning loop antennas is a tricky business, and so far I have only found single-frequency series tuning to be satisfactory overall, though some people do like to tune them in parallel into a high-impedance amplifier. I've tried all sorts of methods, and my opinion is a result of years of experience and quite a few disappointments.

Earlier this year I looked into the possibility of wide-band matching a loop for just a narrow band of frequencies, such as the 40M band. The results were more than just disappointing, and despite that I published the results here:

http://www.home.earthlink.net/~christrask/Paper010.html

That, however, led me into looking into a passive method of series-tuning a loop antenna, and the results were much better than I had anticipated, such that I retired my earlier active loop and now use this for the 49-25m bands:

http://www.home.earthlink.net/~christrask/Paper011.html

The inductance and resistance of the loop are not directly related, and the loop actually takes on the form of a shorted transmission line after a point, while the resiatance has it's own characteristics. The guiding quantity is the antenna efficiency, which happens to coincide at about the point where the inductance makes that transition, and before the resistance becomes asymptotic (sp?). Dean_0,

the gain of a loop is a function of its cross-sectional area. The larger the area within the loop perimeter, the larger the gain. But, as with most things, there is a natural limit.

Every loop has a natural inductance and capacitance and therefore has a natural resonant frequency. As the loop gets bigger (or more turns) the inductance and capacitance rises and the natural resonant frequency drops. This is one of the basic priciples for making efficient loops - make the loop so that it's resonant frequency is just above the band of interest and then use the variable capacitor to tune down into the band.

If you add series inductance, the gain will not rise because the loop area has not changed, but the resonance of the loop will drop. I have never heard of anyone adding parallel inductance to a loop but it would make an interesting experiment.

As for blocking (filtering) a frequency.

1. You can rotate the loop until a low gain direction (null point) is pointed at the unwanted station - this will minimise the gain of the loop from that direction and reduce the unwanted signal. Each loop has two null points 180 degrees apart. This nulling ability is one of the benefits of loop antennas.

2. Using an inductor and capacitor, make a PARALLEL tuned circuit whose resonant frequency matches that of the unwanted station. A parallel resonant circuit (sometimes also called a tank circuit) has its HIGHEST impedance at its resonant frequency and so it acts as a barrier to that frequency when in series with the signal. Note: it does not have to be a loop and you could use turns of wire around a ferrite rod for low frequencies or a few turns air wound for higher frequencies or an RF choke of the right value bought from a parts supplier. Because capacitors are notoriously imperfect, it is best to use a trimmer capacitor so that the exact resonant frequency can be tuned. Put this tuned circuit in series with the signal.

3. Using an inductor and capacitor make a SERIES resonant circuit similar to the methods used for the parallel circuit. A series resonant circuit offers its LOWEST impedance at the point of resonance and if placed in parallel with the signal will appear to be a short circuit at the resonant frequency and so drop the signal level of the unwanted frequency.

The formula for calculating the resonant frequency of an LC circuit (it's the same for both series and parallel) is 1 / 2PI x SQRT(LC) where the inductance is in henries and the capacitance in farads.

There is nothing stopping you from making the series or parallel tuned filter circuit with a variable capacitor so that you can change the frequency of the station being tuned out. You could also use a series resonant circuit and a parallel resonant circuit in combination to get even more unwanted signal rejection. OR, if you are getting problems from two stations, using two tuned circuits tuned to one unwanted station each, to reject both of them.

There are a few caveats, however;

if the unwanted frequency is too close to your wanted frequency, the filter will lower the wanted signal also. Nulling is the best option here.

Each filter will lower the wanted signal a bit; this is called insertion loss. Too many filters and insertion loss becomes a problem.

Filters can also affect the tuning of the loop if they are too close (electrically close) to the loop. One solution is to use a wide bandwidth amplifier at the loop and place the filters after the amplifier. This uses the amplifier as a "signal buffer" - the filters are electrically isolated from the loop and so the filters do not interact with the loop tuning.

With your nuisance station so close you might like to try these additional things. Put your radio in an earthed metal box (a box made from bird wire will do) to stop any direct radiation into the radio. If you have external speakers, wrap about ten turns of each speaker lead around a ferrite rod close to the radio end of the wires. Use a mains filter or run the radio from batteries (also inside the metal box).

Hope I haven't confused you.

I hope I have this correct, by the nature of the equation for Fo, to get to a lower resonant frequency, either capacitance, inductance or both need to go up.

If that were the goal (as in my case because I want to take a resonant loop in the MW range and move it down into the LW range), I would add capacitance in parallel with the tuning capacitor across the main resonant loop, or if going the inductance route, i would add an inductor in series with the tuning capacitor.

I would think nothing comes for free, and thus doing either of those things might lower the level of the signal available for exciting the sensing loop, all other things remaining the same. Maybe I have that wrong, but it's what I'd expect.

Adding parallel inductance would lower overall L, and increase Fo, just as if someone added series capacitance, overall C would drop and increase Fo.

I have a fairly unique situation - the top of my house house a pentagonal cupola with a roof overhang of two feet. This creates a pentagon with sides of about 11 feet. The cupola roof sits at 32 feet above the ground.

Here is my question: What kind of a loop antenna can I create by winding wire around the fascia board? I can also extend rods from each vertex to add length to the sides. Since I have plenty of space, I will also probably install a longwire and/or some other wire antenna stretching from a mast outwards.

So I guess my question revolves around how best to utilize the cupola space. My listening area will be under the cupola about 10 below it (my home is a geodesic dome) and I could install a movable sensing loop up near the plane of the outside loop but inside the building. I could also build the loop inside the cupola, but that would be visually intrusive and induce unwanted signals from my wife!

Sal,
I checked one of the many online calculators link here:
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=15196

and it came up with a resonant frequency of 18 mhz with one turn of wire around the periphery (55 feet) you can lower the frequency by adding capacitance across it, or adding more turns.

For more in depth replies, it would help to know what bands you normally listen to, what kind of radio you have, etc.

It sounds like a delightful loop frame. My first question is what do you want to do with the loop. The only clue is the mention of a possible sensing loop below the cupola which would leave me to believe it is for listening to something hi hi.

In any event simply putting a wire outside around the outer edge would produce a 55' horizontal loop that is naturally resonant at around 18 mhz and extending the corners with rods would easily give you between 70 and 80 ft. Such an antenna (single turn) would make an excellent transmitting antenna. You would either feed it with ladder line to a tuner at the operating position below the cupola or put an automatic antenna tuner like made by SGC right up at the feed point (outside at one of the corners).

If just for listening ... eg SW ... feed it with RG58 coax to a simple tuner and you would get excellent reception across the SW bands.

For another antenna project I recently found some great fiberglass rods from Kencove Farm Fence Supplies. They are white, and in various lengths and diameters. They are tremendously strong, and even supporting some 10' telescoping whips out on the ends show no sign of sag.

http://www.kencove.com/fence/ and click Fiberglass on the left side.

I have also found similar, though smaller diameter rods at Lowe's and industrial safety supply stores, though those are bright orange and have reflective tape on them. The ones from Kencove are white.

Geoff,

Ive built several mag loops based on web searches but this one was one
of the simplest to get on 40M and works very well.

http://www.antennex.com/hws/ws0902/hardline.html

I started using the novel tuning capacitor approach they used on other
loop projects with excellent results. Nice quick approach when you
don't have a vacuum variable capacitor available. An SWR antenna
analyzer will make your life much easier. I've used both the MFJ-259B
and the simpler MFJ-207 with equally effective results.

Also, check my QRZ web page for more details of other mag loops.

I've been getting very good results with a makeshift loop from old cable TV coax, just a 25' length wrapped around a closet door as a frame for two complete wraps. Fed via a hinky arrangement better illustrated than described (and I haven't done the illustrations yet). No tuning capacitor.

It's directional on MW below around 1000 kHz. Best for late night skywave above 1000 kHz. I use it for KVNS 1700, KXTR 1660 and XEEP 1060 after dark.

Surprisingly, it also works with reasonably strong shortwave signals up to 10 MHz. A proper tuning capacitor would probably improve the HF performance.

It's a lot less hassle to set up than the usual approach of many wraps of finer wire. No idea how it'd work in a horizontal arrangement, I'd need a longer hank of coax to try it around the perimeter of my ceiling. I suspect it'd work fine in horizontal orientation for shortwave (with a tuner) and for omnidirectional skywave on MW. A low noise pre-amp might help too. Of my various homebrewed indoor antennas this has been the best performer because it's the most resistant to local noise (from my own PC and various appliances, and neighbors' RFI-generators).

Very true. Even a paper clip in the Hi-Z input will receive the more powerful shortwave and local MW stations.

But I was surprised to discover that my abomination of a fugly coax loop actually is a loop and not just another hank of random wire. On MW it has all the characteristics of an actual loop. On shortwave, well... it's a compromise. The fact that it works at all is a pleasant surprise.

Hi all, I am new here and enjoy the reading knowledge. has anyone had experience with commercially valuable loops, and if so any reviews?

6096. tiny SCR Preselector available now

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-12-12 22:43:53 UTC
From: juanm0wwa
Topic: 6096 Message: 6096

Hi all,

The tiny SCR Preselector is available now in two options assembled or kit.
I just updated the photos and files on the corresponding sections.

Also all pending orders have been sent.

The tiny SCR Preselector is the little brother of the SCR Preselector. It is a modular tuneable five band pass filters bank for HF bands covering 1.8 to 30 MHz.

The user through the Graphic User Interface commands from PC the tiny SCR Preselector via Plug and Play high speed USB v2.

The software runs under Windows XP OS or Windows Vista32 OS at the same time with any SDR program without interfering, allowing to the user to control both simultaneously.

Both options come with USB cable and CDROM including software, USB driver for XP/Vista32 OS and manuals.

The kit option includes the preprogrammed PIC microcontroller 18F2455.

Best Regards.

Juan, M0WWA

From: David Feldman
Topic: 6098 Message: 6098

www.qrss.thersgb.net/active-loop-receiving-antenna.html

I am interested in building the antenna mentioned in the URL above, or something similar, or buying a commercial product that is similar (a mid-sized rx loop antenna with integrated pre-amplifier). I have a new serious source of QRN/RFI at home QTH (VDSL telephone network leakage) that renders 40-20M bands very difficult RX (using my elevated-radial vertical and a dipole, both are badly affected.)
As this problem (the VDSL RFI/QRN) is new to me, I am seeking solutions to restore my lost receive capability, and am considering a receive loop antenna. Any advice very gratefully welcomed.

Thank you,

73 Dave WB0GAZ wb0gaz@...

I don't know anything about that particular antenna, but it sounds like it might be an "active antenna", which are not tuned to any frequency but rely on sampling and amplifying signals on very short antennas. So they're very compact and broad-band, good for SWL (and sometimes amateur) reception.

Just Google 'active antennas' for more info on these kinds of antennas. (Just tried that myself and one of the first articles that popped up was one of Chris Trask's reference lists)
:-)

Hi Jim,

I think you are looking for a broomstick antenna. The broomstick antenna can be made resonant but, due to its short length, has lower gain than the same length of wire stretched out.

Try this URL http://www.radiohc.org/Distributions/Dxers/broomstick.html

The broomstick is similar to just about every short antenna. In order to tune the short wire down to the frequencies of interest some inductance must be added. The broomstick has the inductance wound all along its length (distributed inductance) whereas most other short antennas have a compact lump of inductance somewhere along their length.

6104. styro loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-12-16 22:06:17 UTC
From: dean_0_way
Topic: 6104 Message: 6104

I finally got around to fixing this little loop i made months ago;

original config ;
16"x14" 21 turn of 22 #awg stranded insulated wire spaced 1\8" 365-
9.6 tuning cap.

Used it mostly to clean up braodcast MW ,Mutual copling ,but i didn't
like having to leave it by the radio ,got bumped a lot !

After a lot of reading on the net ,and some scrounging in the
basement.

New config ; 16"x14" 19 turns 20 #awg solid copper wire spaced 1
\8",365-9.6 tuning cap , to this i added a sense loop inside the
styro box connected directly to my KA 2100 antenna posts.
The sense loop is a solid wire loop 8 " across ,like the ones on the
old rabbit ears you used to see on the top of some tv sets,but has a
spring wound on the ends of the circle and on the mounting posts so
you can rotate the loop and lay it flat,loop is mounted on a thin
piece of wood with bolts , which hold the feed wires to set also.

I simply placed this inside the box with packing tape and whaala ! A
tunable loop you can put almost anywhere?
It tunes the whole band on MW and is a good perfomer i think ?
althought maybe not perfect ?

On KWMT 540 Khz Fort Dodge Ia.
The Champ 1700 Khz Urbandale Ia.
In the middle, KRVN 880 Khz Lexington Ne.
All with no signal on the set to listenable signal with loop (daytime)

The other night i was playing around with it and got a station from
San Antonio Texas ,forget the call signs ? almost 1000 miles
distant ,,,not bad i'd say?

Possibly i would get even better signal pickup if i ran a sense loop
inside the box replacing the steel wire loop , but it makes a cool
looking loop anyway ,and i don't have to move it , just reach down
and tune the capacitor .....Easy!

Thanks all for the help !
Dean_0

P.S. I bet i build another loop ??? :)

Hey, that might be an excellent catch, depending on where you are. I live in N. Central Texas and have recently been able to catch KWMT from Fort Dodge, IA, right at evening grey line since November 2008, for 5-15 minutes at a time. For me it's a very tough catch because the station puts out only 5,000 watts and competes with two regional powerhouses on 540. At night KWMT powers down to less than 1,000 watts and I haven't been able to catch 'em between the more powerful regional stations.

BTW, I caught KWMT using a barefoot Magnavox D2935 portable, just the internal loopstick, indoors.

My homebrewed loop for another receiver (Palstar R30C), is just a hank of TV coaxial cable wrapped twice around a closet door, which makes for a handy and somewhat directional frame. It's much quieter than the loopsticks on my portables but less directional, and mostly useful for nulling out local RFI from my household appliances. Good for nighttime skywave reception above 1000 kHz, where distant stations sound like chugging mush on the portables.

Oh your the guy! i laughed about that setup but hey ! if it works ?
It's cool! i've built things i couldn't describe too! lol!

I cant be sure at this point but i thought the Texas station was up
on 1700 mhz ? couldnt find it on the net so ill have to try for that
one again!

Yep San antonio i can get at 1200 mhz 6.10 central....barely ...lots
of drift , my local is kicking it's teeth in too. maybe later ?

Yesss, the dreaded fugly loop, or fugloop as I have dubbed it. One of these days I'll build a proper loop but meanwhile the fugloop works and cost 'zackly nuttin'. I rescued the TV coax from the dumpster at my apartment complex.

It even works ohh-kay on shortwave up to 10 MHz. Not great, but RFI is very low, so even weak signals are fairly intelligible, compared with the higher signal strength but fierce static I get on an outdoor random wire.

The Texas oldies station on 1700 is KVNS out of Brownsville on the hurricane coast. Reportedly only 8800 watts daytime, 880 nighttime. Night catches are pretty easy, tho' the signal drifts in and out, swapping with a couple of unid stations. I've snagged it a few times during the day but it's usually wiped out by what I think is a local co-channel for KLIF (similar programming to 570). KVNS carries well enough at night to hear on a portable using a whip rather than a proper MW loopstick - my older portables consider 1700 to be shortwave territory, so the loopsticks cut out and default to the whip.

6112. Loop Antenna Preamp for Broadband Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-12-18 20:24:42 UTC
From: Adam E.
Topic: 6112 Message: 6112

The loop antenna that I used to display in the pics in the other group had a makeover. I had to cut the long leads down to a connection point and connected the loop to the homemade ferrite coupler antenna. I need a schematic for the loop antenna. What I need to do is use the preamp in between the coupler that is connected to the loop antenna and then connect the second coupled connector to the preamp circuit directly into the DX-392 receiver. The loop has only 7 turns of wire on the and the coupling coils are most 16 turns of wire. Can someone submit me a schematic. Its getting hard to find schematics on google.

Adam E.

Sry no pics , if i can figure how to add it to the group photo thing
ill put it in ?

I started with an omaha steak styrofoam box (just the lid) because i
was reading about Bruce Carter's loops ,link below .... By the way
some medical supplies are shipped in the same type boxes .

Anyway this one measures about 14 " - 16" and is about 4 inches deep
The steel loop i got in a box of radio junk at an estate sale some
years ago .

Not very pretty ? but so far..... no stray resistance from the
wife ! lol .

Hi Dave and everyone on the list,

The Broadband Loop Antenna described in the URL below is from my web-page so I am bound to say its the best thing since "sliced bread" and the Internet :-)

http://www.qrss.thersgb.net/active-loop-receiving-antenna.html

Most of the credit should go to John (G8CQX, previously G4UAZ), my loop is based on his original active loop design. I made changes to the biasing levels (increased the devices standing current) in order to reduce the risk of overload due to very strong EU BC stations around 40 Mtrs.

Someone asked if the loop worked well for reciving weak amateur signals. The answer is "yes", in fact this is my main station receiving antenna. I frequently use it to monitor QRSS signals on 30 Mtrs from all around the globe. These signals certainly qualify as "weak signals" and are generally below the audible noise floor. But the antenna is good for all general ham radio and BC station RX use.

The antenna was built as part of a stratagy to combat local noise from things like plasma TV sets, game stations and PC's etc. It has turned out to be one of the most successful projects ever built here at M0AYF.

One of the nice things about the loop amplifier is that it is very "tame" and forgiving of the construction methods used. I have built and tested severel versions of the loop amplifier on everything from tin lids to strip-board with no problems. My first test version used a bread-board and it also worked well.

My advice would be to build the loop amplifier on a scrap of copper clad board (or a food can lid) and try it with a loop of wire about 1 or 2 Mtrs in diameter. Because its an easy-to-construct design you could have it built over a week-end and evaluate the performance for yourself. In my particular case the results are nothing less than spectacular but results may vary depending on the nature of the interference you are trying to get rid of.

The loop will not do much to reduce QRN but the local QRM will be significantly reduced. In my case QRM was around S5 to S7 all the time (sometimes higher) but using the loop has reduced local QRM to S1 or less. If you have a dipole or long wire then its interesting to compare the signals from the loop with those of the LW or dipole. The first thing you will notice is that most signals are "down" on the loop compared to a dipole or long wire but the signal-to-noise ratio will be vastly improved which makes weak signals more readable.

At my QTH I use a long wire and auto ATU for TX while a relay selects the loop for RX. Prior to using the loop I would find operators returning to my calls but I was unable to work them because of my local QRM. Since using the loop I can now copy (and work) much weaker stations.

Please give the loop a try, you may be surprised at the results. I would be happy to hear from anyone testing or using the loop.

Best wishes,

Des (M0AYF)

Thank you, Des and Paul --- I am struggling with a newly introduced S7-S9 RFI from VDSL services just started; this has left me largely deaf on 160-20M bands (and not at all happy).

I will let you and the list know how I fare.

Hey, Dave
Can you tell me what your noise from VDSL sounds like?? I have a new noise here, quite strong at some frequencies, but it is a lot of carriers spread from about 2 to 28 MHz with the classic up/dopwn notch at 12 MHz.? I looked at it with the spectrum analyzer and it is obviously some sort of comm modulation but I have not been able to track it down because it is literally everywhere....I can't sniff it out.? I drive for miles iwth a small loop and I receive it in every direction.

Thanks

John

Hi John,

In this case the signal is just broadband hash, although there are some peaks in the spectrum (I've looked at with a spectrum analyzer attached to the antenna feedline.) I've heard the multi-carrier type signal you describe before elsewhere in the past, but in this case the best way I can think of to describe it is like snow or rain static on an ungrounded antenna. It's very severe (S7-S9), which is mostly taken me off the air.

I have tried walking a few blocks in the neighborhood, as well as my back yard where my antennas are, while carrying a Yaesu VR500 handheld receiver tuned to 10.165 (one of the spectral peaks); the noise varies widely in level and peaks in several different places on my walk (of course, one peak is near my antenna farm!).

What would be really useful would be some sort of small HF receive loop antenna I could attach to the hand-held's BNC port and see if I can find null directions. As the noise problem started recently/suddenly (about 3 weeks ago) I haven't yet found tools/expertise to narrow the problem down. Mainly, I'd like to try to figure out if the source is local (nearby houses, for example) or external to the local area. For this, I believe such a loop antenna would be very helpful.

73 Dave WB0GAZ wb0gaz@...

That sounds similar to a problem I had earlier this year. It turned out to be a fault in a neighborhood electrical utility supply (I think the service tech called it an "air dielectric switch"?).

The problem was impossible for me to trace any closer than my entire block, hundreds of yards in every direction, because every power line in the neighborhood was radiating the noise. Walking around with a portable radio I was able to pin it down to within roughly a city block, but that's about all. It was non-directional.

Fortunately the troubleshooter for the electric company is a ham and understood the problem based on my description and audio clips I recorded off air. They fixed the problem within a couple of weeks. (The main reason for the delay was a massive power outage in a nearby community, which took priority.)

Hello Group:

Has anyone have experience with this loop. It has been selling on the Ebay. Was able to find the manual on the net and seems to be a loop group/network active antenna.

It seems that they are selling like hot cakes, despite of the fact the active component is missing.

Did anyone from this gourp purchase the antenna and can provide a feed back.

Sincerely

Vahe

The UK equivalent of this antenna is shown in the Photos section of the list under "CSA Loop"
Are you sure that the active component is missing, presumably that point was raised in earlier auctions?

6130. "THE STICK" SHORTWAVE ANTENNA sw ham radio dx swl

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-12-30 19:45:49 UTC
From: jefeickert
Topic: 6130 Message: 6130

Buy the **Original** and get the **QUALITY*

"LISTEN TO THE WORLD"

Up for bid is "The Stick" Shortwave Radio Antenna. This antenna is very easy to hook up and use. 1. find a desired location and mount "The Stick" shortwave antenna (with its two included screws) or prop it standing up in a window, on a dresser, desk etc. 2. Uncoil all the 20 foot copper lead in wire and 3. Clip the alligator clip from the lead in wire to your
radios telescopic antenna, or screw terminal and thats it. Very easy to use and works great.

Will work on all shortwave radios with a telescopic or external antenna connection. works with Radio Shack (Realistic), Sangean, Grundig, Sony, Drake, Hallicrafters, Heathkit, Eton,
GE, Kenwood, Zenith, Tecsun, Kaito, Telefunken, Motorola, Eico, Sears, Panasonic, Philco, RCA and many more.

This antenna is perfect for the apartment dweller that needs an excellent shortwave radio all band antenna And does not want to hassle with the landlord, neighbors, spouse, etc... or where space is limited, or where there are big outside antenna restrictions. Antenna is also perfect for traveling when staying in a Hotel room.

"The Stick" takes up very little space right at 3 foot so it can easily be mounted and hidden
out of sight. "The Stick" is a helically wound vertical antenna housed inside durable ABS tube housing with top and bottom cap fittings. "The Stick" has a mounting bracket and comes with two screws to mount the antenna to your desired location. "The Stick" has a 20 foot heavy duty 16/18 guage copper primary lead in wire that is plastic coated with a alligator clip for easy connection to your radio. *NOTE - the lower the guage number on wire the thicker and more durable it will be*)

NOTE - DO not mount "The Stick" on or alongside any aluminum or metal as this will effect the antenna and it will not work well.

"The Stick" shortwave antenna performs very well indoors but screams to be mounted outdoors where it will work to optimum performance.

"The Stick" shortwave antenna DOES NOT require any special tuning or batteries like a Amplified or a Loop antenna does. Why would you want to waste time tuning the antenna everytime to a station only to have to tune it again and again as you tune your radio across
the band on your DX hunt? *Just mount and hook "The Stick" up and your ready to go*.

The Stick shortwave antenna covers all the Shortwave Bands 11 Meters Through 120 Meters. ...*Please note Bands 11 Meters through 21 Meters Are Mostly open during daylight hrs....And Bands 31 Meters through 120 Meters are excellent for nightime hrs after 6pm.

Photo below (In picture 3) shows how easy it is to hook "The Stick shortwave antenna to your radio... *Of Course The Shortwave Radio, 10 Meter Radio, Noise Canceller And SWR Meter Are Not Included In This Auction*.

**r.

*DO NOT HANG "THE STICK" SHORTWAVE ANTENNA AROUND POWER LINES WHICH CAN CAUSE ELECTRICAL SHOCK. *

PLEASE NOTE This antenna is intended to be used as a Shortwave Radio Antenna , it is not intended for use as a cb or ham radio transmitting antenna however it can be used for receiving signals on a cb or ham radio.

Does anyone know about this Antenna?
JIM

000

Thanks for the reply Tracey

I will look under CSA loop...

There is no mention of the active component requirement or being sold with the antenna kit.

Hi,

If you get one for free no harm in trying it. Portable SW radios such as the majority of those listed have a high impedance front end designed for short capacitive type antennas as do automobile AM radios. Clipping 20' of wire wound on a 3' core will add very little .... especially when it is located right next to the built in whip/radio.

Any antenna will work better outdoors .... away from RFI ... especially since your radio has to be located there as well hi hi.

Helically wound antennas, to be useful, are generally wound so that they become resonant at some frequency .... then, once resonant at the desired frequency the bottom of the antenna becomes one half of the feed point. A ground becomes the other. the feed point is low impedance .... the opposite of the input impedance of portable SW receivers (that have whips).

In addition if the inductance and capacitance of the helical coil/antenna resonates at some frequency it is non-resonant at all the others. In my opinion clipping such a coil of wire to your whip antenna will have the same effect as clipping a simple wire 3 to 20 ft long ..... very little.

Jim

6134. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-01 20:18:59 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6134

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - http://www.ccrane.com/justice_antenna.asp

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

6136. Shielded Magnetic Loop Antennas for sale

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-01 21:16:22 UTC
From: Chuck
Topic: 6136 Message: 6136

I have two magnetic loop antennas for sale. These are both PK'S LOOP ANTENNAS from Australia where long range radio still lives!

I saw these antennas in use in Northern Austrailia a couple of years and bought two.

A-LOOP-REMSW620. This 10" high, 6-20 MHz remote, amplified, shielded loop antenna has never been used at all. Designed for out door use with a rotator I was never able to get all the parts together for the rotator. I'm asking $120 for this shipped to your CONUS address.

SHIELD MAGNETIC AM LOOK. This 13" high MW/BCB loop antenna works wonderfully on a table outdoors, or in my basement office. Designed for AM frequencies. Tunable at the antenna (not remote). $60 including shipping to your CONUS address.

Both antennas require 12v DC (not furnished).

USPS money orders, please.

-- Chuck

6137. Condo Antenna

Got a balcony? could use the metal rail for an antenna. Are you on first or second floor? If on the first floor, you might be able to jury rig a ground, if second floor, a flagpole with a wire hanging off the end could work for an antenna.

For a temporary antenna, I tossed some #22 magnet wire up over the roof of our house. The end is supported by a 10' piece of Plastic electrical conduit. Works better than an indoor antenna, even laying on the roof. You could go stealth and use smaller wire, tie a small weight to the end and chuck it up onto the roof. If you are on the second floor, you might not even see it from the ground.

Try something and see if it works. Then try something else. Have some fun with it.

Pappy Hiram

6141. Re: Condo Antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-03 12:16:35 UTC
From: gmcjetpilot
Topic: 6137 Message: 6141

What frequency are you looking at and what radio. Yes a wire is great. I bought a spool of high quality 22 stranded Teflon coated wire on ebay for fairly cheap. I used some as a random wire and also made a loop antenna. It is almost invisible, running it from 2nd story window to tree, about 60 ft. It works well. 75' is ideal.

You can run it out a window to a tree? You have to allow some tree movement. When it gets to your window transition to coaxial ASAP to avoid RFI from inside the house. This is down and dirty.

At the tree end I threw a string/cord over a branch (put a weight on the end). A tied the wire to the string and hosted into the tree. I secured the free end of the string with a stake in the ground.

I also grounded the shield of the coax (just inside the window) with another wire to a telephone ground. The ground wire is the same 22gage wire out the window down to the phone box and ground wire that goes into the ground. Don't do use utility "power" ground, but I figure the phone ground is pretty good and safe. Better is your own good ground stake. There is debate ground or not. Trust me GROUND is awesome and justice noise down.

My Condo/House is new construction as well and has vinyl windows. So where these small wires come in I have small foam spacers to allow the window to be cracked just a bit. Its not as good as sealed closed but no drilling. To do it right I should go through the wall into the attic and out the roof eve or peak. Too much work for now. I am so pleased with the results I am leaving it for now.

The other good thing I did was make a 9:1 BALUN. This set up goes to a TenTex RX320. You may want to try the SW antenna group not the loop group.

Some truths about good antennas I found:

- good ground
- good matching (impedance) with a BALUN*
- the higher the better (not always for loops)
- outside antennas are always better than indoor

* The BALUN is a fun little project you can make. The BIG expensive ones are for transmitting. For receiving you can make a small one with a torrid and some magnetic wire. Google antenna transformer or BALUN or throw in 9:1. The reason for 9:1 ratio is a random wire is about 400-600 ohms. Most radios are 50 ohm. So 9:1 is about right. With out the BALUN and Ground I had wicked RFI problems not its a joy.

Of course this being the LOOP GROUP you can make a nice 2' x 2' loop for LF and MW or low SW. You can get a magnetic loops an amplified loop for broad band. You can have the LOOP inside and point it manually (pick it up and move it). Loops are good for gain and rejection of nose but need to be tuned for each freq.

There is nothing like 75' of wire for SW (150's is better but who has room for that). For general SW listening a good wire out side is going to be best overall; more spacific radio listening loops are great. If money is no object, Wellbrook makes nice RX Loops. You can put a loop in the attic with a rotor and run all the wires to your radio room. I assume you have CODE that keeps you from having out side antenna. You know a loop can be subtle and most CODES allow satellite dishes. Tell them its satellite.

The down side of any indoor antenna is picking up RFI in the home. RFI is terrible now a days with WiFI, Flat Screen TV's, Computer, wireless everything, Printer/Scanner and so on. The further you antenna is from that stuff the better.

Need help write. Give me some details of your scenario.

Cheers George

You can put a loop in the attic with a rotor and run all the wires to your radio room. I assume you have CODE that keeps you from having out side antenna. You know a loop can be subtle and most CODES allow satellite dishes. Tell them its satellite.

The down side of any indoor antenna is picking up RFI in the home. RFI is terrible now a days with WiFI, Flat Screen TV's, Computer, wireless everything, Printer/Scanner and so on. The further you antenna is from that stuff the better.

Need help write. Give me some details of your scenario.

Cheers George

Some good information can be had at the Nordic DX site:

http://www.hard-core-dx.com/ specifically:

http://www.hard-core-dx.com/nordicdx/antenna/special/swlant.html

As well, you can Google "snake antennas" for more related links.

The AM Loop antenna is sold.

The 6MHz - 20MHz antenna remains.

> A-LOOP-REMSW620. This 10" high, 6-20 MHz remote, amplified, shielded
> loop antenna has never been used at all. Designed for out door use

>

This requires 12v DC. Comes with the pair of coax cables needed to power the radio and receive the signals, a bracket for your rotator, sealant for the connectors, and the inside control tuning panel. This antenna need not be permanently mounted and can be placed on an apartment balcony or used on a table top.

Shown at the top of page 5 in the PK Loop cagalog.

http://users.bigpond.net.au/CygnusX3/PK's%20Loop%20Antennas%20Catalogue%202009.pdf

This is it in the foreground with the control box. Very compact 10" high loop.

6146. First Loop Experience: Predicted Peformance vs. Actual

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-05 13:08:29 UTC
From: sernstfortin
Topic: 6146 Message: 6146

Finally finished my first loop antenna.

It is composed of 26 turns of 24AWG uninsulated copper wire around a square frame made primarily from wood dowels (spent a lot of time and effort there). ;)

Depth of loop was approx 5inches.

Variable air-gap capacitor used was speced by the source that I purchased it from to be 16pF to 390pF.

I used the 5/2003 version of Bruce Carter's AM Loop Calculator to predict performance.

What I discovered through testing with my radio was a tuning range of Freq(lo)= 200KHz, and Freq(hi) = 433KHz...

I believe this off-design result to be primarily a function of the wire I used and final construction / routing of the sensing coil and connection to tuning capacitor.

While there was quite a difference between predicted vs. actual, what I did find when using Spectrum Lab was the antenna did a fair job of nulling off-tuned frequency content, and the directional nulling was pretty good too.

And, while I was using this antenna in my basement, I scored another NDB in preliminary testing.

I'm wondering how the antenna will do outdoors and elevated about 12 feet above ground as opposed to 6 ft below ground in the basement...

Regards.

Interesting...

26 turns of very thin wire, but what size of the frame?
How long sides of the loop, how long wood dowels in a
cross-form?

What kind of transmissions were you wishing to receive?

I built a similar loop, square frame, 34" per side and 31 turns of 18 gauge wire. Tuned from 160 kHz to 440 kHz. I also used 1/4 turn link coupling into a low Z pre amp. Worked great for NDBs.

IMO, loops are the best thing since sliced bread for DXing the weak stations!

Yes,

24gauge uninsulated wire.

frame is: 34"x34" sides. 26 turns effectively 5" deep on the frame (total frame depth may be 24-30"... I don't remember to be honest)

NDBs and other LF signals is my target.

John,
Thanks for the encouragement. The Frame got a lot of attention.... The other parts, not so much. You know, prototype one and plan to toss it. ;)

OK, I've got questions:
18AWG insulated or uninsulated?
Multi-strand wire or solid?
What width for the 31 turns?
What do you mean with a 1/4 turn link coupling (just two sides on the outside of the frame, or the length of the outter perimeter (34"*4 / 4) on the inside of the frame? If so, where in the inside of the frame?
Link shaped like a circle or square?
Can you provide more details on the low-Z pre-amp?

I forgot to mention, I used 1 loop about the perimeter for sensing sent to the radio. The resonant loop and the sensing loop share no common in what I prototyped.

I was a bit surprised to be able to audibly and visually see the effects of adjusting the tuning capacitor... Like I should have doubted the concept at all. I mean, I was building one based on what other people are doing. If it didn't work... well, maybe I'd take it to the fire place. The dowels would make good kindling if nothing else, and the evidence of the experiment would be gone.

Having a knob for the variable capacitor was important. Touching the shaft of the var cap affected tuning (of course).

Outside I think it will perform better. I mean I'm fairly well below grade on 3 sides.

I hear what you are saying with respect to the greatest thing since sliced bread. One begins to think rotor, remote adjustments for the tuning...

Hi,

I don't know what your design goals were .... or the dimensions of the loop ... e.g. distance between the dowels. However, my loop which is approx. 1' square (also use dowels at the corners) is wound with 18 turns close spaced of insulated hook-up wire. It resonates from about 530 khz to 1500 khz using a similar but slightly smaller capacitor to yours. So I am not surprised at your tuning range. I don't use a sensing coil with mine as all the radios I used work with mutual inductive coupling (it works vy well).

I predict little difference except perhaps for less RFI opportunity. My loop performs better out on the deck ... less noise out there from local household wiring etc. Elevating the small loop doesn't seem to have much effect ... except for further reduction of RFI ..... it seems ground effect is low with small tuned loops.

The square (cube) frame is approx. 34x34x30. I'm concerned I may not be using an ideal sensing coil to maximize the amount of signal detected sent to the receiver.

Your loop seems ideal for AM/MW reception. Ideally, I'd be able to tune a loop from 30KHz to 540KHz.

I am currently awaiting a variable capacitor with a much wider span (34pF-740pF) than the one I am using now. ;)

I wonder if this my problem and if anyone is?
this come from SW Pirates.
Dear shortwave radio user.

This is an update from UKQRM the group trying to fight back against Power Line Technologies that are wiping out the radio spectrum.
These devices (PLT) are used within a household to set up computer networks using the mains power cables of that house.
If you want an example you need only go to our video page
http://www.mikeandsniffy.co.uk/UKQRM/videos.htm

Probably the main offender here is the Comtrend Power Line Ethernet adaptors supplied as part of BT's Vision package.
But there are many other types that have nearly the same potential to destroy our hobbies and way of life.
The interference extends up to 500 yards around the house using the devices!
The cumulative effect of many hundreds of these devices is so bad that NATO has even raised concerns!

Hi Sam,

They say a picture is worth a thousand words. Follow this link and you can see a schematic and a couple of pics of a BCB version of the LF loop, minus the amplifier.

http://groups.yahoo.com/group/loopantennas/photos/album/227852299/pic/list

The wire I used was stranded copper, tinned, and insulated with a Teflon coating, MIL spec I believe. I tuned it with a 365 pF variable. Turns were close wound with the only spacing provided by the thick insulation (about equivalent to a wire diameter).

The amplifier was a design by the late Ralph Burhans called an H90A. I have the schematic for that if you're interested.

I experimented with one turn coupling and the 1/4 turn provided less loading and a higher Q for the loop coil thus improving selectivity. It was a marked improvement over the one turn!

I have an article I wrote up for the Lowdown many years back that I can send you if you'd like.

I plan to install a loop antenna on my backyard, receive only. The plan is to not tune it and to use a broadband preamp, for matching the impedance and for insulating the antenna from the common mode noise pickup on the feeder.
But I still would like to be able to control the null direction remotely. My feeling is that if signals from 2 orthogonal loops are added with a variable phase shift, the null direction may rotate with the phase change.
Did anybody experiment with a setup like this?

Interesting idea using electronic steering. I haven't tried it but it should work.

Years ago I steered a broad banded loop using a TV antenna rotator. It worked very well but was a little slow.

I was doing exactly that about a year ago and settled on using an orthogonal pair of active short dipoles, though loops would work as well. The circuitry required for achieving the phase shift was a bit ambitious as I wanted the phase and gain to be constant over the band of 5MHz to 15MHz. Dallas Lankford has a frequency-dependent phase shifter for what you have in mind, and it's much simpler than mine though it needs to be adjusted for any change in frequency.

The commercial cancellers such as those made by MFJ and Timewave to not have legitimate phase shifters. What they have is an amplifier with balanced outputs and a pot between the outputs. Basically, all you get is a variable gain that ranges from +/- 1.0 and no phase change inbetween. They seem to have copied each others design with no ragard to the complete lack of continuous phase shift.

Thanks a lot for pointing to Dallas Lankford site! I didn't know about him before.
I think I'll go with 2 loops or dipoles, 2 preamps and 2 feeders, with all the phaser controls and adjustments in the shack. At least for the experimenting phase of the project.
The problem I am trying to address is a strong noise on SW. I walked around with FT-817 and a small loop antenna to find a low-noise location and/or antenna orientation on my small backyard. The noise comes from different directions at different times and on different frequencies, which means I can not use a fixed loop. I am really lazy, so playing with rotators and other mechanical stuff is out of the question.

With a little adjustment. I can turn my orthogonal dipole/phaser setup
into an electronically steerable antenna, but I haven't taken the project
that far yet. It was originally intended just for cancelling strong
adjacent signals, and I learned along the way that two methods need to be
brought to bear as the phasing of two antennas for cancellation is pretty
useless if the antennas are co-located and the two stations are in the same
direction.

That is a very nice looking loop John. I use Teflon insulated wire on my loops and other antennas. It lasts forever.
If you can could you send that schematic and article to me? Many thanks.

Mike
WE0H

As the other replies have made clear, it is certainly possible. My reading on the topic has suggested that better null steering is achieved with the antennas as far apart as possible and slightly off from orthogonal, say 75 degrees instead of 90. This may vary depending on the specifics of the loops and the frequencies in question. The limited experience I have is with phasing antennas for MW reception so it may not be the same with SW reception.

Topic: 6146 Message: 6164

I sent two different loop calculators to sernstfortin@... plus my difficulties in dealing with any antenna and about my 8" loop that seems to work OK in the MW band. His narrow frequency range was unusual and makes me think to study this some more before making a loop.

How does one calculate the pf capacitance of a v-cap? I have 9 of them and one works well with a crude crystal radio and with 2 inexpensive AM radios using the 8" loop. I don't fully understand how to attach the dual v-caps to the antenna or loop, sensing coil or without the sensing coil.

I use my DX 398 to verify frequencies on the AM radios using the 8" loop; I have a scanner with an OCF wire taped to my office wall, a square loop around my office ceiling for the DX 398 (the regular telescoping antenna seems to work as well) and a single loop around a large photo frame that seems to work only on FM. All antennas are inside but I had an outside aerial at one time.

useful on 80 and 40 meters where they perform well at modest heights.
These are closed loops that are one full wavelength long. Horizontal
loops may be fed at any convenient spot. For best performance, make
your horizontal loop into a square, especially if it is to be used on
several bands.

> TL Loop Receiving Antenna 10 KHz - 30 MHz
> The principle of operation is that an rf voltage appears across the
terminals of a loop when it is placed in an electromagnetic field. The
voltage is proportional to frequency for a given field strength and so
at Very Low Frequencies the voltage is very small and requires greater
amplification but it is not quite as simple as that. The new TL Loop
uses a unique feedback system to optimise the amplification/noise

factor over a much wider range than has been possible hitherto.

Hi,

This is how the crossed loops in shipboard LF directional antennas work .... the loops are mounted perpendicular to each other ... the feed lines (parallel) are brought down to the radio room and connected to a 'goniometer' .... crossed inductors .... with a rotating pickup loop inside. The effect is as if a single loop was being rotated.

I've found Bruce Carter's calculators to be fairly accurate, or at
least, in the ballpark.

With your figures, 34" x 34", .19" wire spacing, 26 turns, and your
tuning cap figures, 16-390 pf, Bruce's calculator shows 165 khz - 815
khz.

Both loops are in the same location, so the incoming signal have the same or opposite phase depending on the direction the signal is coming from. A null is being achieved when the signals coming from both antennas have equal amplitude and opposite phase when being added to each other.
So IMHO the only thing one needs is a switching arrangement to be able to change the phase of one of the signals from the two antennas and a means to change the amplitude of the signals relative to each other. In its simplest form this could be a potmeter where both signals are the inputs to the end contacts and the output is from the moving contact.
My solution seems so simple, where do I go wrong?

Cor Beijersbergen van Henegouwen

In case anyone is interested, you can see them in "John's Corner".

The preamp was designed by the late Ralph Burhans, an engineer and LF tinkerer/enthusiast. It worked very well on my LF loop. Frequency response was limited by the use of audio transformers for coupling but seemed pretty flat up to the antenna upper frequency of 400 kHz.

Everyone always asks me "What is a quarter turn link coupling?". It's easier to show then to explain, for me anyway.

BTW, the tuning on this antenna is sharp and I plan on making it sharper by winding it with Litz wire.

I'm not an expert, but I know that the construction techniques used could throw a wrench into the predicted.

How does one measure the capacitance of a variable cap? Well, one could gen up some form of RC arrangement that is
either charged or discharged and from the time constant associated with the exponential waveform (oscilloscope or VOM),
with a known R, you estimate C.

Or, one could gen up some form of frequency generator (multistable / oscillator) who's freq and period depend on C, and measure
the frequency or period (oscope most likely, but a frequency meter perhaps) to estimate C, or one could use a suitable Capacitance
Meter (which ultimately I presume estimates the value of the capacitor under test by one of these methods).

For all I know, the VOM or oscope may skew the measurement, so I personally may just go out and get a capacitance meter myself.
They are relatively cheap (you have to make sure you get one that has a resolution of fractional pF if possible).

If you have a dua-l or tri- or quad-section vcap, I'm thinking you are referring to the number of tunable elements which are essentially
ganged on the same shaft right? In general, I believe you want to place the sections in parallel to have their individual capacitances sum
together to give you the widest possible tuning range / span.

I do not have your vcaps in my hand to look at them, but more than likely, since they share the same shaft, they probably already have
one leg in common, perhaps the outside shell / frame of the vcap... whatever is in common with the tuning shaft....

Therefore, to place them all in parallel, you simply tie the stationary portions together electrically (I suspect there would be a solder
lug for each section). I hope my description is clear.

OK, now the coils of your loop antenna form the resonant section and the inductance which must be paralleled with the capacitance of your
vcap to be placed into tunable resonance.

Your sensing coil: I suspect you either have something wound around the frame (right on top of the resonant windings), or you have
something smaller forming a loop inside the resonant windings. How many turns? I can't tell you that... like I said I'm a newbee myself.

If you have a portable shortwave radio, mearly placing your radio inside the resonant coil is enough to provide antenna coupling. No
sensing coil needed.

Otherwise, I believe, you have the two wires attached to the antenna plug (you go buy one to fit the radio) wired to the sensing coil.

Don't ask me what to do if you want to have just some form of aligator clip on with your telescoping antenna.

I hope others here will help you more as you've about tapped out my working knowledge of loop antennas.

More reading for me.

Good luck, and have fun!

Subject: [loopantennas] Re:First Loop Experience: Predicted Peformance vs. Actual

I sent two different loop calculators to sernstfortin@ yahoo.com plus my difficulties in dealing with any antenna and about my 8" loop that seems to work OK in the MW band. His narrow frequency range was unusual and makes me think to study this some more before making a loop.

How does one calculate the pf capacitance of a v-cap? I have 9 of them and one works well with a crude crystal radio and with 2 inexpensive AM radios using the 8" loop. I don't fully understand how to attach the dual v-caps to the antenna or loop, sensing coil or without the sensing coil.

I use my DX 398 to verify frequencies on the AM radios using the 8" loop; I have a scanner with an OCF wire taped to my office wall, a square loop around my office ceiling for the DX 398 (the regular telescoping antenna seems to work as well) and a single loop around a large photo frame that seems to work only on FM. All antennas are inside but I had an outside aerial at one time.

The quarter turn link coupling lowers the impedance going to the input of the amplifier.

From my experience a full turn loop is about 600 ohms. The quarter turn loop will probably be about 50 ohm, but to check this you would need a noise bridge

Similar situation here, small apartment, no practical way to put up permanent outdoor antenna (tho' I'll sneak some random wire up a tree on weekends).

My best compromise solution so far is a homebrewed passive loop made from a hank of old TV coaxial cable rescued from the trash. It's about 25'-30' long. I wound it twice around a closet door - it's just long enough to leave a 12" space between each end. The feedline and finishing is too weird to describe so I'll try to attach a photo later in the week. No tuning capacitor. I use jumpers with alligator clips to adjust it for MW or SWL.

The closet door gives it some directionality. On MW it's fairly directional, tho' not as sharp as a typical portable's internal ferrite loopstick. On shortwave it's not directional at all, but pivoting the door can help null out household noise from my own computer.

On MW it works best for skywave propagation and it generally beats the internal loopsticks on my portables for low noise reception, especially at night above approx. 1000 kHz.

On shortwave it's not terribly sensitive but at least it cuts way back on the household RFI. Weak signals are actually more intelligible than on a bit of random wire up a tree. The random wire may pick up an S9 signal along with S8 noise. The homebrewed loop will pick up the same signal at around S1-S3 with negligible noise, so it's far more pleasant.

If I wanted to do without the minor advantage of being able to pivot the closet door I'd just fasten the coax inside a window frame - the window next to the closet door is about 3' wide and 6' high, so there's plenty of room.

It's really crude but it works and is much less noisy than a typical indoor random wire or telescoping whip on a portable.

I used a crude impedance bridge and it was somewhat closer to 200 ohms which was a close enough match for the preamp.

Right, that works. :)

In fact, I decided as an early birthday gift to myself, I would purchase one - so this morning I ordered an LCR meter off eBay for a reasonable price to complement my VOM.

Capacitance from .1pF to 20mF, and inductance from .1uH to 20H.
http://www.aidetek.com/New_products_info/Datasheet/Vichy/DM4070.doc

I'm aware the accuracy is not that of a more costly high-end meter, but it should be more than sufficient for my purposes.

I have seen plenty of post praising the Quantum loop antenna.
I would like to purchase one,but before buying one I would like to know how it is comapared with the Wellbrook 1530+ antenna.

I have already got a Wellbrook 1530+ and I am mainly interested in tropical,49mb and medium wave listening and since Quantum loop are mainly made for these bands I would be very pleased to hear some reviews whether the Quantum surpases the Wellbrook in these bands. Yes, the Wellbrook it is good but is worth buying a Quantum loop?

Any comments are very wellcomed. Thanks.

I had a small yeasu FT 817-ND and thought it was pretty bad on receive. I got myself an Elecraft K2 and that was when I found out how bad the ADSL modems actually were. But do not forget the switched mode power supplies; they throw out a lot of hash also. I have now replaced all the power supplies with old fashioned transformer power supplies andfor the high current I have a lead acid battery on an automatic charger and feed my transceiver with that.

Much improvement and it gets even better when i switch the computers off.

Each of these antennas is designed for a specific purpose. The Wellbrook is for those who don't have room for a much larger antenna. It's very good, but in a quiet location a long run of wire is quite likely to outperform it. (Of course, I don't know where exactly one finds a RF quiet location these days.)

Similarly, the Quantum loop is primarily for those working the lower end of the spectrum who can't have an outdoor antenna. I have two Quantum loops, a QX Pro with a 15" head (no longer in production) and a QX v2.0 specifically tuned for LW. They are both excellent antennas and I wouldn't want to be without them, but they both suffer from the same problem -- they must be on your tabletop so you can work the controls and rotate the loop head. Unless you're sitting in the middle of your backyard (something I've done on occasion), the antennas are going to be indoors and suffer from all the problems inherent in that location.

If you live in a typical modern home, the Wellbrook with a rotator mounted outside in a good location is almost certain to outperform the Quantum. Almost any antenna mounted outside away from the noise envelope of the house and away from other noise sources will outperform almost any other antenna placed inside the house.

The one feature the Quantum has that might give it a slight edge in specific situations is the "QX" control. This uses regen to effectively narrow the receive bandwidth of the antenna. It can be the difference in cases where a strong station is masking a neighboring weak one.

You might also get some benefit from phasing the Quantum and the Wellbrook against each other, assuming you were willing to build or buy a phaser too. (There is a Quantum Phaser available.)

These last two things are kind of reaching. Frankly, if you've got the Wellbrook in a good location with a rotator, you're unlikely to get a better signal from a Quantum antenna in the house on your tabletop. I in no way mean this as a slam against the Quantum -- they're the best I've ever seen in a tabletop antenna -- but you can't get around the negative characteristics of being located inside the house.

I hope this helps.

Darren,

The actual device has a drain, source and gate. Don't worry about the drain floating. There are only three gates on the actual device.

Sam, the C and L range you quoted for this model is way off on the lower end of the ranges. I checked it out on e-bay and bought one as the price was quite good ($50.29 with free shipping. The only ones with the range you quoted cost much more
and are probably worth it but more accuracy than I need. thanks for the tip. 73 Gary N9ZSV

Thank you Sam as that was clear advice, you answered my questions and I will put your advice to work. I have asked local hams about the cap meter and got insufficient answers from them. From what I can tell you are not a newbie. I am definitely a newbie. I will begin to plan a multi loop antenna that will work for the MW BC band and perhaps higher as well. My inside horizontal loop and outside ground is attached to the stereo plug going into the radio external antenna input, ground to inside and antenna to tip. This subject is taking time away from taking the Technician License test as I have been a frustrated Ham for 50 years due to finding many other interests to pursue.
Bill

Sam at sernstfortin@... wrote: "so I personally may just go out and get a capacitance meter myself.
They are relatively cheap (you have to make sure you get one that has a resolution of fractional pF if possible)."
And, "Therefore, to place them all in parallel, you simply tie the stationary portions together electrically (I suspect there would be a solder

lug for each section). I hope my description is clear."

And, "OK, now the coils of your loop antenna form the resonant section and the inductance which must be paralleled with the capacitance of your vcap to be placed into tunable resonance.

Your sensing coil: I suspect you either have something wound around the frame (right on top of the resonant windings), or you have something smaller forming a loop inside the resonant windings. How many turns? I can't tell you that... like I said I'm a newbee myself.

If you have a portable shortwave radio, mearly placing your radio inside the resonant coil is enough to provide antenna coupling. No sensing coil needed.

Otherwise, I believe, you have the two wires attached to the antenna plug (you go buy one to fit the radio) wired to the sensing coil."

Gary Pewitt garypewitt@... wrote:

>>Sam, the C and L range you quoted for this model is way off on the lower end of the ranges.

Gary, this is true. Let me clarify.
First, it is a modest priced LCR meter, and if the accuracy is 2-4%, I'm not too troubled by that, it will be useful to determine the "C" and "L" when working wth these loops and accurate enough for what I need to do (as is the same for you).

Now then, the confusion over the numbers...

OK, when I stated 0.1pF on the low end for example for the device, the lowest Range setting on this particular unit is 0->2pF right? But, the resolution is 0.1pF... Therefore, if in theory you had a very (very very) small cap that had a capacitance which was less than 2pF, say close to 0.1pF (wow), while the range of the measured values on that setting would be 0->2pF, the smallest cap it could measure and present a value to us would be 0.1pF...

So when I stated it could read from 0.1pF to 20mF, I was merely indicating the span of capacitance values that it could provide a measurement to a user. And, no, I'm not expecting to rely on that fractional pF information at all.

We are talking about the same meter, but in a slightly differenent way.

And just because it possesses a 0.1pF resolution on the low end Range, I don't expect it's accuracy is going to be better than a device that doesn't provide that information.

Often when you are using a device to measure a quantity, the resolution and digits presented will be higher than you'd record on paper or use in subsequent calculations. I just like the fact this thing can read down below 5 to 20pF (I assume this would be the typical low-end on most variable caps).

Now this is important, I won't go using this thing to read the capacitance of a varactor diode (one of those devices that changes it's capacitance with a reverse bias voltage), because I'd ruin the meter... I'll just use it for variable and fixed capacitors and inductances. I write that because, well, I do plan on experimenting with remote tuning of a loop using a varactor diode arrangement... there you send a voltage down a wire and you affect the capacitance coupled to the loop's inductance... Then in theory with a rotor, you have a remotely tunable, steerable loop...

Yahoo.

6193. Square loop experience and question

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-09 13:21:18 UTC
From: K_endre
Topic: 6193 Message: 6193

Hi All,

I've built a loop antenna wound on a wooden frame with a side lenght of 0.85m and a coil depth of 15cm. The tuned coil (primary) has 17 turns tuned with a variable cap of 20-400pF. I'm interested to receive an AM station around 550KHz. The results with my classic ferrite rod receiver it is quite convincing, vy sensitive and sellective.
But, my real intention is to connect to my father's FRG7700 with other words to match to 50R. As I calculated for transfering 50R I would need about 6 -7 turns as coupler coil or secondary (XL x 4 at 550 KHz). This is more than in any other description... how to build this coil to be able to cover the MW band?

Many thanks for reading, Endy/YO6OGJ

I hook this up to my DMM, the ranges are 200.0pF to 20.00uF full
scale, using the 200mV scale on the meter for 200pF to 2uF, and 2V
full scale for 20uF.

<http://www.polyphoto.com/tutorials/Dual555CapMeter/Dual555CapMeter150dpi.jpg>

I have a 0.1% tolerance capacitor I keep around to calibrate projects
like this.

Hi Endy,

I have the exact need. I have a tuned loop for MW that works vy well through mutual induction with radios that incorporate a tuned ferrite antenna. However I have radios that require a separate antenna input .... as does your FRG7700. My solution was to use the small untuned loop that came with my Hi-Fi receiver ... e.g. 4 turns of insulated hook-up wire on light plastic form 8 inches in diameter with a twisted pair as the connecting cable. Light coax will also be suitable.

As you are aware, connecting through mutual inductance works best when the loop and radio orientation are adjusted for best performance. I found the same to be true using the link winding. Best performance requires the ability to adjust the orientation between the tuned loop and the untuned pickup loop. It is up to your imagination and mechanical aptitude to design the arrangement hi hi.

In my case I ended up with a simple 8 inch dowel along which i can slide the pickup loop to adjust the coupling. I am sure there are more sophisticated methods for this mechanical adjustment.

Jim

Endy,

I use less than a turn inductive coupling for a good match to 50 ohms.

Let's use my AM loop for example. I have 12 turns of 18 gauge wire on a square form of approximately 425mm X 425mm. The impedance across the loop at resonance is 313.7 kohms (I use a loop calculator for this measurement, much easier than doing the math). If I use a one turn link, the loop now becomes a transformer with a turns ratio is 12:1.

The turns ratio of a transformer is the square root of the impedance ratio. Conversely, the impedance ratio will be the turns ratio squared. So 12 squared = 144 thus 313.7kohms/144 = 2.17kohms as would be seen by the receiver.

To reduce this value to something close to 50 ohms we need to reduce the coupling coefficient. Coupling coefficient is a complex subject unto it's own but suffice it to say that by using the 1/4 turn method I used, the impedance as seen by the receiver is roughly 200 ohms. I measured this with a simple bridge but close enough for experimenting purposes.

Another nice feature of keeping the coupling loose, the loop has a higher Q and greater selectivity. In my early days of experimenting I noticed a double hump response while tuning across the band with a one turn link

You can see a picture of my AM loop here which shows how I coupled the secondary.

Hi All,

I've built a loop antenna wound on a wooden frame with a side lenght
of 0.85m and a coil depth of 15cm. The tuned coil (primary) has 17
turns tuned with a variable cap of 20-400pF. I'm interested to receive
an AM station around 550KHz. The results with my classic ferrite rod
receiver it is quite convincing, vy sensitive and sellective.
But, my real intention is to connect to my father's FRG7700 with other
words to match to 50R. As I calculated for transfering 50R I would need
about 6 -7 turns as coupler coil or secondary (XL x 4 at 550 KHz). This
is more than in any other description. .. how to build this coil to be
able to cover the MW band?

Many thanks for reading, Endy/YO6OGJ

There was a gentleman who posted on this and a few other yahoo groups wanting to know what antenna he could use for SWL in a nursing home he was in, something small and easy to put up, take down.

I have tried to contact him several times to no avail.

I have built him a SW loop that will be easy to put up and take down. It is his free of charge, I just need an address to send it to.

So, if he reads this, all he has to do is contact me.

Sam, thanks for the clarification. I am glad to hear it because I
ordered the same one last night.
My use will be checking values of junk box components and ham fest buys
before building regenerative receivers and small transmitters.
The accuracy will be all I need as I am not designing anything critical
and wouldn't know how to anyway. I just enjoy building and restoring
the old "boatanchors".
Thanks, 73, and a tip of the hat. Gary N9ZSV

I'll try to upload a photo this weekend. Gotta recharge the batteries for my digicam first. I'll give a shot at describing it, but probably won't make much sense.

Picture a double wrap of TV coax around the entire outer perimeter of the door. There's about 12" of space between the ends of the coax. The barrel or cannister type TV balun is threaded into the upper end. The two spade type connectors are hanging down.

The jumper is another short hank of old coax, maybe 18" long. No connectors or adapters on either end, just bare wire. Using only the outer shield, the upper end of this jumper is wrapped around the spade connectors of the TV balun. The lower end, again using the outer shield rather than center conductor, is attached to an alligator clip.

The lower end of the jumper is alligator clipped to the outer shell of the TV coax "F" type connector. In effect, connected to the outer shield of the long hank of coax looped around the door frame.

The feedline to the receiver is yet a third run of TV coax, this one only a few feet long with ordinary F type connectors. One end is connected, via a female-female adapter, to the lower end of the loop. The other end of the feedline runs through an adapter to suit the usual PL-239/PL-259 connectors.

It's quite a piece of junk and shouldn't work. But it does. I found it by accident. I was trying to use the tuning capacitor cannibalized from an older radio when my hand slipped and made contacts that woke up the radio on the MW spectrum. I realized I didn't actually need the tuning capacitor for satisfactory reception. It works great for nighttime skywave reception above 1000 kHz and is moderately directional on the lower end. Very low noise compared with the internal ferrite loopsticks on my Sony and Magnavox portables.

It also works okay - not great - on HF below 10 MHz. It'll pull in strong signals with very low interference from household RFI. Very handy this winter when every neighbor in my apartment complex has their electric heater on.

If I unclip the jumper between the upper and lower ends of the loop it'll pick up shortwave much stronger, but it's no longer really a loop. It's just a hank of random wire looped around the door frame and just as subject to noise as a bit of random wire strung along the ceiling.

Anyway, after I upload a photo you'll see why I call it the "fugly loop" or fugloop. It's just... fugly. But I gotta laugh because the

dang thing works.

BTW, it does need a ground, but not an especially good ground. My "ground" is probably closer to a counterpoise, since it's just 6' of household type insulated electrical cord buried in the dirt outside my 1st floor window. A pitiable excuse for a ground but, heck, it does the job.

There's no real need to match impedance for receive.

A single turn for a "sense coil" or "pickup loop" is usually sufficient, and it need not be as large as the loop. In fact, a pickup loop about half the diameter and offset works well. I have used a coax loop, curled around, with the center conductor soldered to the braid, 10" dia, and tie wrapped to the main loop inside one corner of the main loop with good results.

Here is a good calculator for loop antennas:

http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

6204. Square Loop Antenna; Predicted vs. Actual

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-11 19:31:54 UTC
From: sernstfortin
Topic: 6204 Message: 6204

FWIW,
I constructed a loop which is square, 34" on a side. The depth of my loops consisting of 26 turns of solid 24AWG exposed copper wire is 4.3125".

Predicted "L" is 1306uH = 1.306mH.

Measured "L" for the loop using my newly acquired LCR meter (I love this thing), is 1.365mH.

Measured "C" for the variable cap is 17 - 431pF.

Predicted tuning range is: 212KHz to 1.068MHz.

Actual tuning range is seemingly much smaller: 200 - 433KHz is where I could peak the noise on the receiver. On the low-end, predicted matches fairly well with actual. Not so on the high end, but then, I'm listening to the change in noise level to determine span of the antenna actual. There may be one source of error. ;)

Using the equation: F = 1 / [2*pi*SQRT(L*C)] with measured values...
I'm suppsed to have loop resonance between 6.6 and 33KHz.

I'm not doing something right.

Any pointers appreciated.

May be there is a parasitic capacitance in parallel with the variable cap. Between the turns?

At 07:51 PM 1/11/2009 +0000, you wrote:

>May be there is a parasitic capacitance in parallel with the variable
>cap. Between the turns?

Yes, any loop has some capacitance .... even a single turn loop. The smaller the amount of capacitance the more inductance is required to obtain resonance. Once you start making the loop multi-turn you increase the internal loop capacitance. This is why various techniques are used ... such as basket weave, wide spaced turns, etc ... to minimize the amount of internal loop capacitance.

If you are winding a loop which you want to resonate at x frequency it is theoretically possible to simply put enough turns on until the inductive reactance matches the internal loop capacitive reactance and voila the loop is self resonant without adding any additional capacitance. A single turn loop 140' in circumference is self resonant at 7 mhz.

If you want to make a loop for MW frequencies full size loops are out of the question and you must go multi-turn to provide sufficient inductance .... while at the same time adding in some additional capacitance (which you usually want to keep to minimum). There are some formulae ... or rules of thumb that can be used for winding such loops. In all cases, the capacitance that must be added to obtain resonance is in addition to the capacitance created in winding the loop. The more that is added in the winding the more the tuning range of the loop is limited.

For a MW loop I have found through experience that the greatest tuning range (with a standard 350 pfd variable capacitor) is obtained with a loop of substantial size ... eg 2 ft square or larger with wide spaced turns. the smaller you make the loop the more turns required, the closer the spacing, and the smaller the tuning range for a given variable.

Jim

Tuning becomes kind of broad near the upper limits so you are probably not hearing the "woosch" as you tune past the peak. Also, stray capacitance tends to lower the actual upper frequency limit. Plugging in your figures into my loop calculator turned up the same results as you, so the math is right.

Jim,
I appreciate your response, that of Jose, and John. What you write, and you write it with clarity makes sense. Are some of the formula's which you mention in an easy to digest form? How interesting your treatment was, because, one knows for example the span of the tuning capacitance (upper and lower limits on a var cap or ganged variactor diodes), and one knows the preferred / desired range of tuned frequencies... Could one then pick an area for loop size, and determine the number of turns and turn spacing from that?

I envision codifying something in Excel and using goal-seek to solve for a realizable design that gets one close to their desired frequency span (if that is possible), with the minimum amount of wire, and the smallest practical loop.

Something like that I think would be helpful to the loop builder.
Sam

6209. Want better 621 Kz reception!

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-10 07:43:38 UTC
From: Tony
Topic: 6209 Message: 6209

Hello all,

I'm located (Apollo Bay, Victoria, Australia) about 250km from a 621 KHz transmitter but the reception with a variety of domestic radios has loads of hiss, not much better outdoors than indoors. Not much local QRM and no adjacent-freq txers. Main application is to listen clearly to broadcasts from this tx in the kitchen and living room, not to DX or scan the bands. My receivers have no access to their inbuilt ferrite loop antenna. Car radio reception in the area is better than domestic radio reception of this Txer.

I'm considering whether to:

- making an external antenna by connecting to the roof guttering, terminating on a parallel LC circuit, perhaps using a ferrite rod, in physical proximity to the radio for inductive coupling to the inbuilt antenna, then earthing the cold end of the coil; or

- have a 'slave' type loop antenna sitting on the bench next to the radio, as described in several posts and websites.

I've no experience with loops and would value any suggestions/comments please.

kind regards

TonyW

For a small investment, give a passive loop a try. My Terk Advantage looks to be about 12 turns of wire with about 350uF tuning capacitor. I have used this with great success on my last outing to the middle of Lincoln County Nevada (90 minutes north of Las Vegas, 90 minutes west of St. George, UT in the middle of a valley). I was able to listen to KTAR (620) in Phoenix, AZ; KFI (640); KFWB (980) and KNX (1070), Los Angelese; and KIGS (620) in Hanford, CA. I was just casually tuning around listening for coverage of our past Presidential Elections last November and whatever else was happening. Had it set up nicely on a table in my room next to a northfacing window with an adjacent window airconditioner/heater blowing warm air.

Receiver was a Sangean ATS-909.

I haven't tried it, but if you have an old analog transistor radio, you might want to bring it up close to you other radio and give it a tune without power. You would essentially have a loop antenna with the addition of the ferrite loopstick core which may prove advantageous. You may have to shift the position of the two radios around to get proper coupling between radios. Just something off the wall to try.

From: march181959
Topic: 6209 Message: 6212

I was going through some old files and I dug up an ad in 2001 for the Spidercone antenna. The tests indicated that it had "outstanding results" in the AM through SW range. It may have been offered through Grove.

Does anyone remember this antenna or have any experience with it? From the ad it looks like two triangles 180 degrees apart. The base of each is 29 feet and the sides of each triangle 51 ft. It sits 14 -18 ft above the ground. Each triangle is fed into ladder line to the receiver.

It looks easy enough to build and I thought I might give it a try.

Regards,

Frank C
Boston

It might interest you to know that I have done splendid reception of a 5 kW station on 620 kHz from 330 miles away, which I think is in the realm of 500 to 600 km. So it is possible!

First of all - the pattern of that station was towards the West, where I was receiving it. Hopefully you are not in a null on your station, and it has enough power to go the 250 km.

I was using a GE Superadio 3, and this radio is legendary for its sensitivity. Just using its internal ferrite, it produced an almost clear signal, very listenable.

To soup it up a bit, I experimented with various loop antennas - the tuned type. These are curious contraptions, as they pack multiple dB's of gain passively! There is no free lunch, and they also have a null point, too, a bit higher in the tuning for my loop. Using a 1.5m (approximately) loop, I have been able to receive 50 kW AM / MW stations at distances up to 1600 km daytime. So loop antennas have plenty of gain to do what you are trying to do!

I've got construction articles if you are interested.

What calculator are you guys using? I like this one the best since it works out for my 2 foot and 3.5 foot AM BCB loops ...

http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

I understand "square loop 34 inches on a side". I understand 26 turns and solid #24 wire. I do not understand "The depth of my loops consisting of 26 turns of solid 24AWG exposed copper wire is 4.3125".

What is 4.3125"??

The above calculator link show tuning from 135hz to 680hz with .o5" spacing between wires, if I understood you correctly.

I use the Reg loop calculator designed and written by the late Reg G4FGQ.

Go to this link and look for "Download Programs from here". The program for multi-turn framed loops is "RJELOOP3". It's a DOS program but will run independently on your PC.

http://www.zerobeat.net/G4FGQ/

There are three or four formulas out there, all of which work for some geometry better than others. Some are good for larger loops, some for smaller. None of them get closer than about 10% and there is a fair amount of "tweaking" involved. I've discovered that closer spacing raises the Q dramatically without affecting the tuning - much. But you can expect to add or subtract turns of wire until you get it right. And counter intuitive - smaller values of tuning capacitor and more turns of wire are easier to make a loop covering the entire band.

> Thanks for sharing that.

I saw a project for one in a magazine long ago that used logic gates.
It drifted badly with temp and voltage changes and was sensitive to
which revision of gate used. Since the 555 is very stable, I designed
it using a couple 555 gates. It is solid enough, after all my DMM is
only rated at 3% accuracy.

I do have the LCR meter from AADE, too. It works great, although I'm
not that please with the physical design of it. I worry about the
banana jacks getting broken in my toolbox.

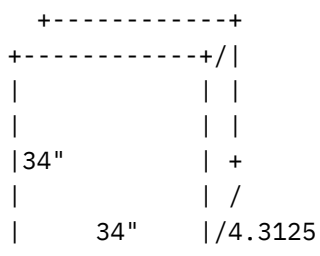
Mark.
If you had a cube, there would be three dimensions: looking head on, my loop has equal length sides of 34inches. However, the pitch of the windings, or the winding depth, or the dimension over which the resonant windings stack up is 4.3125inches.



That is what I meant by depth.

I like and appreciate very much the large LCD display. Yes, the banana jacks seem a little marginal, but you can pull them out and attach the measured cap or inductor to the metal clips. This isn't practical with a var cap nor the windings, specially if the gauge of the wire is small.

But, for a $40, i'm not complaining. When I started adding everything up for making one, and putting it in a case, etc, powering it, paying for shipping of parts, the purchase off eBay made absolute sense.

I recall seeing a similar instrument for testing capacitors that appeared in Popular Electronics or some other magazine about 30-35 years ago. It used the same 555 format where the first one was a clock oscillator and the second was a pulse width modulator. They work fairly well given their simplicity. I made one and used it for years until I obtained a cheap LCR meter.

They can be a bit more accurate if the zero pot is replaced with a third 555 of the same circuit as the second, where a fixed reference inductor (or inductors) is used. This will cancel out the unavoidable errors from the finite switching time of the 555.

>

I'm not sure how that is more accurate unless you mean to avoid
checking the zero set when you use it. On my 555 cap meter, the zero
set is a front panel control. Calibration is an internal 20 turn pot.

Would you then adjust the reference inductor for zero? It seems to me
that temperature induced drift in an adjustable inductor would be
greater than that of a potentiometer and the 555 timer itself.

One of the uses I have for the cap meter is a fairly sensitive
differential capacitance sensor that does use a third 555 just as you
describe. In that situation, zero set isn't performed regularly and
this way drift due to the 555 is canceled out.

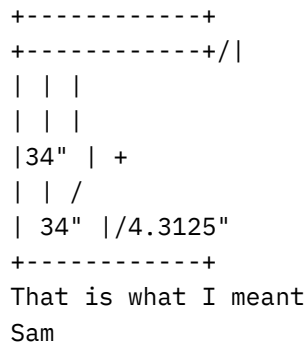
6230. Square Loop Antenna; Predicted vs. Actual

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-13 16:24:27 UTC
From: brian russell
Topic: 6204 Message: 6230

Hi All,
I have been following this thread with interest, well done to all for the comments.
One question I have is, does the ' shape ' of the loop winding width have any
effect on performance ????
Most loop photos I have seen show the width as flat but I have seen the odd variation
like a triangle, circle and I was given a sample of a former which
is ' heart ' shaped, the inductive turn being in the ' V' of the heart.
Hope this makes sense, a sketch would easily show the idea.
72, Brian, G0NSL-QRP.



That is what I meant by depth.
Sam

Hi Bruce;

Just realized I am championing your on-line calculators. Thanks for sharing your handy work. I built a 6-sided 3.5ft effective diameter loop using v2 of your AM Loop Antenna Calculator - UMR EMC Lab Formula. I got lucky, it tuned perfectly first try. Built it for the AM BCB but it tuned down to abt. 450 khz. Ha - I quickly realized the slight signal gain w/ respect to a 2 ft loop did not outweigh the antenna's bulk factor, so it's being rebuilt to a smaller dimension. Since I've been thinking about the rebuild lately, what you just wrote made my head spin. You said "I've discovered that closer spacing raises the Q dramatically without affecting the tuning - much". Oops, now i'm really confused. Haven't I been reading wider spacing, use of interleaving techniques & premium Litz wire are design considerations for minimizing internal capacitance and that is the main consideration when going for highest Q?

Can you straighten me out?

Thanks,

Mark

Hi,

The "Carver Ultimate AM antenna" is indeed a sweeping statement hi. It is simply 4 turns on a 1ft square frame. Most Hi Fi am receivers which don't have a built in ferrite antenna supply such a simple antenna .... several turns on a light form 8" to 12" in diameter with a twisted pair of wires for a feed line which connects to the AM antenna input.

I have several of them .... I would hardly call them an ultimate antenna hi hi. They are adequate for strong local stations. I have found them useful as a pickup loop when used with a larger tuned loop.

I am new to this group and need help. I did a search for my needs but came up empty.

I wish to build a 1 to 2 meter diam shielded loop antenna using 72 ohm hardline. I have all the info I need from a mechanical point of view but I am looking for a differential input amplifier design that is broadbanded and will cover 160 thru 40 meters. I will place it in the base of the loop and connect it directly to the two center conductor ends of the coax.

I have found several amp designs but they are all for very low freq loops. Can anyone point me in the direction of an amplifier that will meet this need. Many thanks in advance for anything you have to offer.

Well,
In order to get the very fine wire to stay in place on the all wood frame I built out of wooden dowels, I applied some contact adhesive to strips cut from a bicycle wheel inner-tube. I then used an exacto knife to cut slits at regular intervals to hold the corners of the wire turns. Works great...

But, at the moment I am hesitant to re-wrap it with a deeper depth (less loops per inch), or remove a number of loops.

I received from ebay a really nice variable capacitor from Lithuania. When on eBay, search for:
4-GANG AIR VARIABLE CAPACITOR with reduction

I really like this capacitor.

I put all the sections in parallel and built myself a "hoola hoop loop" (say that 4 times quickly). That tunes from about 300KHz to 600KHz. I want to see if a circular loop formula gets close to predicting my results. More details later in another thread specific to the hoola-hoop which I mangled.

Anyhow, I plan to take the variable capacitors from the square antenna and hoola-hoop loop antennas and switch them and see what I get... On one test I did last night, the gain from the square loop is much higher than the hoola-hoop loop.

What was so nice is both easily pick up a NDB out of Charleston SC on 329KHz and make it clearly audible... and I'm in my basement below grade! Love it. And, there's a very strong NDB on 366KHz local from the ATL airport, just turning either of these loops and the nulling effect is dramatic.

This is fun. What I want to relate to everyone... if you're subscribed to this group and *thinking* about building a loop, get yourself a variable capacitor and build one. I can't believe I waited this long to construct one.

The name derives from the "Carver Ultimate Tuner" for which the antenna design was intended. It does work well with nearly all tuners and receivers which do not have built in ferrite core loop antennas.

Naturally, it does not have the gain of a tuned loop, but it's advantage is that it requires no tuning.

And it works quite well. I've built a number of them for myself (1 for the shop system, one for the bedroom system, one for the main livingroom system, as well as for friends and family.

Many knock it because it is not a tuned loop. It is what it is, and works well.

There is one in the photo section under AA7U that works pretty good
but could stand to be tweaked, the IP2 isn't as good as the Lankford
push pull active whip I also have but it's still decent and more
suited to very low impedance broadband loops than the ones with the
high input impedance FET transistors

OK, if someone decides to replace a variable capacitor with varactor diode(s), does it then qualify as an "active" loop? ;)

Positioning the Faraday coupling loop has never been easy, and my only experience with it has been listening to people complain about it. At the same time, I also listened to others complaining about the cost and effort needed in the loops that have the motor-operated vacuum vaiable capacitor at the far end.

Those were the primary incentives that prompted me to look at the manner in which loop antennas were matched to the feedline, and the result was two relatively simple and inexpensive designs. The first one is a receive-only loop matching that uses a pair of varactors and three wideband transformers:

http://www.home.earthlink.net/~christrask/Paper011.html

The second design is a transmitting version good for up to 100W using the same matching topology, but uses a relatively inexpensive dual variable capacitor driven by a small gearhead motor:

http://www.home.earthlink.net/~christrask/Paper012.html

Barely, and probably not. Active antennas are usually small with respect to wavelength and include amplifiers to make up for the smaller size. The loop that I made with the varactor tuning is still full-sized, just a lot less expensive than using a motor-driven capacitor.

From an electrical standpoint it really doesn't matter since current distribution is equal around a small loop. With that in mind, couple the pickup loop wherever is convenient from a mechanical standpoint.

Here is a link to give you an idea.

I made a loop of 1 mt in diameter for the receiving the short-wave with

a loop, 1/5 in diameter, in RG 213 to limit more the noise. I ask you,

it is important the positioning of the loop coupling? And if so, where

it should be positioned at the top or bottom of the main loop? Why?

Thank you

There is a lot of math involved with that question. But in a nutshell, the aperture, or size of the antenna is the main determining factor in loop performance. This is the case where bigger is better.

There is an excellent article that deals with the theory that can be found here.

This question has come up a number of times, and when the dust settles, the general answer seems to be that the shape is negligible, square, circular, rectangular, or octagonal all work more or less the same, the differences being so slight as to be nearly impossible to measure objectively. There are other factors that have greater influence, height above ground, interaction with other antennas or nearby objects, etc...

Hi All,
Having a wander around the Internet on the ' Antennas for AM '
theme
I came across a plan (very simple) for the Carver Ultimate AM antenna
(Carver Corporation, Lynnwood, Washington, USA).
Since that is a pretty sweeping statement to make I wonder if anyone ever
made one and found it to be true ????

Yep I made one with a pizza box and some 22awg stranded teflon insulated wire. It worked so well I re-did it on a USPS packing box. The pizza box was a perfect 12" x 12" (17" diagonal) but was narrow. It worked as well as the packing box. However the packing box is wider, more sturdy and easier to loop. Also wider wire space changes the charicterists of the antenna (good/bad not sure you have to try it). The both worked well and I have pictures of both below.

The ULT AM antenna carver shows is 1 foot sides, with 4 turns and twisted lead. I copied it except with out the wood frame. My box was not perfect, like 13" x 12" sided. I also went 5 turns not 4. No particular reason, only the length of wire I had, giving me 5 turns or about 20 feet of loop with a nice 12" twisted lead-in, verse the carvers 16 feet loop length (4 turns x 4'). I also figure all my local stations of interest are down in the sub 850 khz range, so an extra turn wouldn't hurt.

The ULT AM BOX ANT (packing box) drives my mini Awia radio/CD stereo on my dresser. The Awia has a metal case and does not have an internal AM or FM antennas. The Awia I recall (and from the owners manual) came with a loop antenna on a plastic frame, much smaller than the 1 x 1 antenna. I must of lost or misplaced it long ago. The ultimate antenna works well with some caveat's.

SEE PICTURES BELOW

The ultimate AM antenna is really just like bigger version of the ubiquitous AM loops you get with some many consumer radios, that clip on the back of the radio. That does not mean they perform well. Also the Awia mini stereo (at least on AM) is off par when compared to "real" SW radios or portable radios with large internal loop sticks. The FM radio circuit is digital and actually pretty good for a basic consumer radio. The Awia is 12 yrs old btw.

Also like the loop antennas you get with radios the ULT AM ANT has no tuning but very directional. I have compaired it to three popular (on eBay and retail) AM antennas I own.

- Terk AM advantage
- Tecsun AN-200
- Kaito/Degen DE31/KA33

The first two are passive 9" loops with a tuning cap.
The second is a portable amplified sw/mw antenna with tuning and a single loop of wire on a frame you fold out and hang up.
The three above all work well but the amplified loop does a little better. (more below)

SEE PICS BELOW

The ULTIMATE AM ANTENNA, I made does OK. It is directional and has gain with good noise rejection (for my installation). Holding it I can totally block out the nearby stations turning the loop to the null side. Trying to get DX AM BCB stations with this antenna, radio and in my 1st floor bedroom with many outside walls in 4 directions is pointless.

Compared to the other antennas use as a bench mark it is not a true DX MW antenna. However for local stations it's awesome and cheap. The pizza box was free and the wire I had is worth say $5. A little time and tape, done. This way I don't tie up any of my good antennas for the bedroom radio.

BTW I tried a random wire for AM on the Awia stereo, about 20 feet long, tacked on the wall and ceiling. It was awful and noisy.

For my ULT AM Ant installation the loop is tacked on a N-S wall. The 2 or 3 'big' AM stations worth listing to are only 5-15 miles south. So I have it pinned up behind the dresser out if sight aligned with the stations to the south. With out the antenna, the AM radio does nothing, there is no internal antenna, AM or FM. I don't really listen to AM radio for entertainment, but if I want to listen to the Fox radio propaganda shows or local sports in Raleigh it's there.

FM (you can see it in some of the PICS) is a 1/2 wave FM dipole antenna out of some coax, balun and wire. It works well out to 50-60 miles. The FM antenna is directional like the AM antenna, limiting to some stations due to mounting it on an interior N-S wall.

I receive and have store 6 AM and 20 FM stored stations. With out any antenna its zero. For an hour or two of fun and stuff I had in the drawer I'm happy with my AM/FM antennas. They are not real visible and work. Best of all I didn't have to spend $100 on antennas.

The only disappointment is not the AM, but a local FM college radio station only 10-12 miles away, comes in with static. I need a directional antenna with more gain. AM wise, if I want to do some DX'ing, I fire up the TenTex RX320D, connected to an outdoor random wire about 60' long and 15' off the ground. It does well. A Wellbrook would be nice but the neighborhood has anti-antenna rules.

YOU WON'T KNOW TILL YOU MAKE ONE.

AM Loop antennas for bench marks
http://img525.imageshack.us/img525/7522/slide3copymh0.jpg
http://img522.imageshack.us/img522/1176/slide1fx3.jpg

I am building a 2 foot X 2 foot loop with two tuning capacitors on a large wood frame with about 20 turn wraps around the frame (with a 4 turn tap for higher freqs). It should out perform all my loops in the below 3000 Khz and BCB range. It is just larger.

THE WINNER.....

The Kaito/Degen DE31/KA33/TC34 (they come in different names and models, see eBay) does VERY well, with a broader range from MW to SW. Over all for the money the amplified AM/SW antenna is pretty good, but ugly and not easy to handle. It hangs up like a coat hanger. The amplifier unit is the size of a pack of gum with a tiny thumb nail tuning dial. It is battery powered with 2xAAA. Not bad if you have rechargable batteries, but I estimate if using alkaline you are going to need to replace them every 15 hours or less? It is not real practical for permanent installation and messing with the amplifier box is a tad of a pain. You have to remember to turn it off when not in use.

Middle of the road and WORK VERY WELL are the passive 9" loops. However they take up some room, which they need so you can aim them and tune them. If you are using the PASSIVE sympathetic / repeater / proximity method of boosting the a radios internal antenna you need a table to position the antenna and radio optimally. Both the Terk and Tecsun have a jack for direct connection to the radio. The great part is they work with out jacks* and no battery power. (* The amplifed Kaito/Degen has a repeater loop stick for proximity boost of internal antenns)

BOTTOM LINE The Ultimate AM Antenna is a WINNER for a local radio station you want to get and want a dedicated antenna for that radio. It can be made for almost nothing and should do better than the cheap loop/wire antennas you buy off of ebay for $10 which are usally much smaller.

You can find photos of mine in the Photos section in my Loop Kits
folder.

The name derives from the antenna being designed to be used with the
Carver "Ultimate" tuner.

I've built a number of these loops for my own use and for friends.
They work very well. They will not produce as strong a signal as a
tuned loop, but require no tuning. Very simple.

Excellent writeup on these antennas!

I have the Kaito/Degen 31 that I used inside my METAL workshop
building after Gustav for SWL, before I put my main SW antenna back
up. I was able to listen to a net in the next state, and most of the
hams checking in, using the Kaito 31 and Icom R75 receiver.

With the "Ultimate AM Antenna" during the day I can easily pick up a
5000 watt station about 200 miles away. At night, from the Louisiana
Gulf Coast, I can usually hear WOAI in San Antionio, WSB in Atlanta,
KMOX in St. Louis, MO, WLW in Cinncinnati, OH, and both WLS and WGN
in Chicago.

Not as strong a signal as the MTM Scientific tuned loop, but still
quite directional.

Still, the topic of "Carver" audio products is an interesting one, and after Googling some Carver info after reading this antenna article, i think i will have to read up more on Carver. I had always felt their products were over-hyped but maybe the quality is really there. I have a few Carver car radios, those were built by Eton in Germany, but Carver lost about $1 Million in 1983 dollars when the cassette drive on them proved too problem prone and the unsold and unreturned radios were just warehoused for several years until they were finally sold to a surplus dealer. Those car radios do have a pretty good AM section, seem to have fine selectivity but good audio quality at the same time. The also have the LW band - useless in N America - and the European 49 meter shortwave band, as well as FM. -Hue Miller

I think you are painting Bob Carver and his gear a little on the negative side. I know a little about Carver since I lived in Seattle in the mid 80's, Carvers prime. My friends company did contract work and painted the black lacquer paint on Carver cabinets.

Wikipedia has a good detailed write ups. Bob Carver is physicist and electronic inventor. He did some amazing things and still does with his new company.

http://en.wikipedia.org/wiki/Robert_W._Carver

His high end stereos where state of the art and he holds a boat load of patents. He could emulate any amplifier and had what he called holographic sound and speaker patents (ribbon speakers).

He never was known for his radio receivers, but amplification and speakers. He did have patents on FM radio for Asymmetrical Charge Coupled FM Detector design. I am not sure he had any thing special for AM radio. I am pretty sure he was an early adapter of synthesized digital tuning for both AM/FM (I don't recall any analog tuning radios but could be wrong.)

Wiki: "In 1985, Audiophile magazine challenged Bob Copy to copy a Conrad-Johnson Premier Five (the make and model was not named in the challenge but revealed later) amplifier at their offices in New Mexico within 48 hours. The Conrad Johnson amplifier was one of the most highly regarded amplifiers of its day, costing in excess of $12,000 (in 1985 money). Nevertheless, Carver, using null difference testing, successfully copied the sound of the target amplifier and won the challenge." He made and marked some amps based on these challenge that sold for $600-$1,200. He also sued the magazine for bias.

Many old Carver products are collector items now by audio enthusiast.

SUNFIRE high end audiophile and theater sound systems, is the company that came out of Carver consumer electronics. They are highly regarded.

Cheers

From: tenorman1952
Topic: 6269 Message: 6269

I have available one Icom IC-R75-02. This receiver is about 3 year old New In Box. The -02 refers to an earlier version with DSP and Synchronous-AM factory installed.

It was removed from the box only to turn on and confirm that it does have:

UT-106 DSP Module installed (DSP is indicated on LCD)

Synchronous-AM (S-AM is indicated on LCD)

(These will not indicate on the LCD if the modules are not present.)

The Sync-AM is not on later versions of this receiver due to the chip used being out of production. But it is in this receiver.

$550.00 plus $30 shipping. I can accept Paypal or Credit Card processed through my business.

I can be reached at tenorman1952 at yahoo dot com.

From: chas
Topic: 6270 Message: 6270

I have a building out back, 24x30' and I am thinking about attaching a 3 or 4' piece of 1" ID PVC on each corner and wrapping the 108 linear feet with some 22 or 24ga wire... spaced about a foot apart. that would give me about 400' of wire going into some 450ohm ladderline, thence to a balun to drop it to 50ohms and then into the Dentron tuner. this is obviously going to be a cloud burner unless I can get it up into the air and away from the ground. but heck, unless I can stand it on a side AND up off the ground, it is going to be highly NVIS anyway.

I am really looking for a quiet, 2mhz antenna for 500W or so MARS work at night when the critical freq drops into the mid or low 2's.

suggestions??

From: jdh1812
Topic: 6271 Message: 6271

Hi Guys,

Just finished a new loop. I had to improve on the old one so I made
the frame a little sturdier and used Litz 175/56 in place of magnet wire.

Basic design is the same, 12 turns with 1/4 turn inductive coupling on
a frame made with 4" X 2'. I find this loose coupling provides very
sharp tuning and less loading than if I was to use a full turn. I
experimented quite a bit before settling on this ratio.

The capacitor is a dual 365 pf in parallel (730 pF total) and tunes
the loop from 500 kHz to 2100 kHz.

I compared it to my 100' East/West antenna and it compares favorably.
I haven't had a chance to test it properly in a direct A/B comparison
but what little bit of tuning around I did, made me a believer! It
also plays well on the 160 meter ham band. Several stations were S9+
on my Icom R75, same as the wire!

So, if anyone's interested, I uploaded some new pics here.

http://groups.yahoo.com/group/loopantennas/photos/album/227852299/pic/list

It's the dark stained frame.

6272. Want to learn about shielded vs. unshielded and tuned vs untuned loop merits

Yahoo group: loopantennas (2008 — 2012)

From: David Feldman
Topic: 6272 Message: 6272

Have built the G8CQX untuned loop per URL
www.qrss.thersgb.net/active-loop-receiving-antenna.html

It is an unshielded, untuned loop antenna, and was built to improve on HF noise in my nearby environment (with underground utilities here, I believe mostly from nearby radiating electronic devices I don't control.) Improvement seen so far is modest, but I've done only a little testing.

Before building more experimental antennas for comparison, (there are many articles and designs available on the web), I'd like to get an idea of the merits of various options so I can spend my construction time most effectively. Advice or links to information would be gratefully appreciated.

Dave; What options? I"ve had great fun w/a 2 ft square multi-turn loop tuned loop. Big enough to provide amazing gain, small enough to use and spin indoors. Don't know about non-resonant loops.

All loops resonate at some frequency, even without a cap, due to stray capacitance. So, an "untuned" loop is merely a loop operated away from its resonant frequency, usually below. The advantage of an untuned loop is wide bandwidth, with more-or-less linear response across the band (if you're far enough from the resonance). The disadvantage is many dB's loss of gain and lower SNR (since you're inviting in all those neighboring frequencies).

Untuned loops are very popular with ELF and VLF "natural radio" enthusiasts, since they like to monitor the entire VLF band with a spectrum analyzer instead of a receiver.

Tuned loops are better,IMO, for NDB, BC, SW and ham listening, especially for reception of DX stations, due to the extra gain and high SNR.

HTH,
John/AF4EX

6276. Improving the Degen DE 31 Active Loop.

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-01-31 14:51:19 UTC
From: Ian
Topic: 6276 Message: 6276

Hi All,
Having recently purchased a DE 31, I was a little disappinted
that it didn't tune up on the 80 Metre Ham band.
I have now extended it by 32" (80cm) and it tunes up really well on
80!
It has a nice sharp peak from 3.5 MHz up to 14.5 MHz. On MW, it peaks
from 500 KHz up to 2 MHz. This makes this little loop more useful to
me as I spend many hours listening to 80 Metres.

The loop wire consists of two multistranded conductors which are
enameled and shorted together at both ends. My junk box produced a
length of similar wire which is just as flexible and nice and light.
I decided to extend both ends of the loop to give it a more
symmetrical appearance. The loop was unoldered from the small PCB and
the new pieces added. A small length of heatshring tubing was
employed to tidy the joints. You will need to mve the knots, in the
loop wire, down a few inches to give you a symmetrical diamond shape
to your loop.

Because the loop is bigger than before, it also works better on
medium wave.

Try doing this modification to yours! You could replace all of the
loop wire, it's up to you.

73,
Ian G1DRP

At my bedside I have a Degen 1103 radio, actually a really nice little radio that has MW and SW bands. You can actually 'fool' the radio into starting at 0 khz and working up in frequency using an easy software 'hack' but the lower khz segments below MW seem to have some 'overload' from local stations if using either a long wire or anything other than the internal ferrite antenna.

The neat thing about the radio is that IF you plug in an external antenna, both the AM ferrite antenna and the telescoping SW antenna are disconnected in favor of the external. Sooo, I decided to build a little loop antenna and see if it made a difference.

I had on hand a wire spool for some ham coax (I am a ham op - KC9CS) and took the spool apart because it had a nice sturdy 9" cardboard tube. I cut about 2" off the tube and used this for my loop form. I had some twin speaker line with tiny, probably 22 gauge wire which I split lengthwise. It is solid core wire. I wound 22 turns of this on the 9" tube. For a capacitor I had four small, identical 100pf variable capacitors that I wired together, not wanting to pirate my 365pf variables from either of my crystal sets. I wired up the input cable and tried the new loop this afternoon about 5 pm, the sun was still up here in west central Florida.

My first station I pulled in was in Atlanta! A full 500 miles distant and still daylight. WOW! Now that it is evening, I'm experimenting and listening with it starting at the low end of the MW band. WSM is an easy catch from Nashville at 650 khz, which is about at far as I've scanned yet. DX'ing from Florida is kind of tough because we get a LOT of spanish stations from who knows where. Mexico is just across the Gulf of Mexico, lots of spanish speaking Caribbean Islands too. What impresses me with this antenna is how well it is regarding directivity. Turn the antenna slowly and the signal drops out, another pops up. Turn it back and the noise disappears, the desired station jumps back in. I haven't noticed a lot of difference using the capacitors yet, but I've only played with this antenna for about an hour so far. I'm sure as I gain experience it will improve. Something else dawned on me too....I don't remember paying much attention to linking those 4 capacitors together -- whether they were all series linked or series-paralleled. That WOULD make a difference, but tomorrow will be time enough. In the meantime, I am amazed at the way this little loop works.

Go loops!

Right, I believe that if the capacitors are wired in parallel, the equivalent capacitance is the sum of the individual capacitors,
i.e. Ceq = C1 + C2 + ... Cn

If the capacitors are wired in series, the reciprocal of the equivalent capacitance is equal to the sum of the reciprocals of each individual capacitor,
i.e. 1/Ceq = 1/C1 + 1/C2 +... 1/Cn

You are right, there should be a big difference in your results depending on how they are wired together.

Not busting your chops Bill, you may be right, but....Are you sure BILL about the internal loop stick being cut out with the antenna input? I don't think so (I have a Degen 1103). On page 26 it says:

"If FM or SW reception is too weak, use supplied extra- long external antenna to improve reception."

I assume it does not mention MW. Here is the user manual. http://www.dpmega.com.hk/usermanual/e1103.pdf

The manual says SW is from 1710 to 29999 khz. You are correct you can trick it to go below MW, but I did not know it would go below 100 Khz. How do you do that.

Also your antenna sounds cool, nice, could you take some pics & draw a diagram and post it in the pictures section. Thanks George

Trick to tune the Degen 1103 down below 100Khz:
http://www.rosestone.me.uk/Degen/VLF.txt

This suggests the unit does some auto-selection/de-selection of the Ferrite Rod Antenna based on what and how it is tuned. If someone had a schematic, one could determine if the external antenna input jack has a contact which opens or closes with the insertion of the plug.

Hi George,

The Sun, Earth's magnetic field, the ionosphere, and radio propagation is not a simple story. Having said that here is the simple story hi hi. Let's start with a hypothetical scenario in which there is no Ionosphere, layers of ionized molecules, at different heights and thicknesses, over various parts of the globe. In this scenario all electromagnetic radiation, regardless of frequency, will for all practical purposes propagate in exactly the same way. That is the transmitter and receiver must be in the line of sight. All radiation at an elevation above the line of site will simply continue on into space.

As it happens there is an Ionosphere, ionized gases that occur in layers (usually in 2, 3, or more layers at different heights) at different locations and different times around the globe. These layers, the Ionosphere, are the result of the interaction between cosmic rays that are emitted from the sun and the Earth's magnetic field. If the rate of the Sun's emissions and the Earth's magnetic field remained constant then the nature of the Ionosphere would remain predictable and would only vary as the Earth rotated exposing any particular area to the Sun on a 24 hour cycle. However, the Sun's emissions and the Earth's magnetic field are not constant and as a result there is a great variability in the nature of the ionospheric layers.

You need to understand how electromagnetic radiation interacts with ionospheric layers. When the radiation field hits an ionospheric layer the radiation may be reflected. how it is reflected will depend on 1. the frequency of the radiation, 2. the thickness and height of the layer, and the angle at which they interact. The radiation frequency is important ... generally speaking the lower the frequency the more it is absorbed by the layer .... as the frequency goes lower it reaches a point where all radiation is absorbed before any of it can be reflected. Conversely the higher the frequency the greater the penetration of the ionosphere .... with the result that very high frequencies may penetrate the layers again with no resultant reflections. (the result of the reflections of course allows propagation beyond the line of sight).

Addressing the original question concerning the Sun and Sun variability. First, 'storms'. Both the comic ray emissions from the Sun and the magnetic field of the Earth suffer 'storms' ... and not always independently. A Sun storm is due to some kind of solar 'flare' that will cause a sudden increase or pulse of cosmic ray emission. A very strong pulse can even cause power failures of various kinds ... certainly they cause a ripping apart of ionospheric layers which can literally 'black out' all HF propagation. These Sun storms also cause the Earth's magnetic field to whip around as well. The Earth's magnetic field can cause the storm as well ... it appears that some geologic phenomena can cause this .... it is known that in the past these magnetic storms have actually caused the field to reverse (north to south). Generally storms caused by the Earths magnetic field are minor in comparison to solar storms.

Aside from storms, the radiation from the Sun remains relatively constant with a slow drift up or down in apparent association with the number of sunspots visible on the surface of the sun. The greater the number of sun spots the greater radiation and the more effective the ionosphere for HF radio propagation. I mention HF frequencies as they are the most dependent on the ionosphere. This slow drift of radiation up and down follows a cycle that seems to be approximately 11 years long. Because of the association with sun spots and the average cycle being 11 years, it has come to be known as the 11 year Sunspot cycle.

Presently we are the bottom of what seems a protracted cycle. Everyone is looking for the sunspots to increase in number with a resultant increase in HF propagation.

There is a short ? version. there are many sites on Web that go to great lengths to predict a report all aspects of the phenomena. For most of us we simply become familiar with propagation as it affects our use ... whether as an Amateur operator or a SWL.

6285. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-01 21:34:18 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6285

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

I simply tuned it, in the SW setting, to the lowest frequency, and it would the receiver would turn the entire 80 meter band with no difficult. I made no modifications.

Hi Dean,

I don't think you need to do that. log into Yahoo groups and you will be able to modify the Email address for your particular groups. I have several Email addresses and I recall I went into my groups and modified the Email address to be used. You can register a number of different addresses and then specify which one to use for any of your groupsl

Topic: 6277 Message: 6290

Bill I double checked and I was right, the Antenna plug is for SW (and FM) only on the Degan 1103, however you can boost the internal MW loop stick by a repeater or proximity loop boost.

I have tired it with the Tecsun AN-200 and Terk AM advantage (simular 9" loops). It works well. However the stock loop stick with out help is pretty amazing.

The Degen DE31 or similar portable amplified loop has a loop stick booster. It works pretty well with the DE 1103. I found the loop stick to be on the back near the base of the telescoping antenna.

When I use the loop stick booster of the Degen DE31 portable antenna (or similar), I fold the telescopic antenna up and lay the booster in that little recess near the base of the telescopic antenna.

What I found is the the existing loop stick does pretty well on its own on MW. Of all the portable radios the DE 1103 gets the least benefit of an external LOOP booster. The DE 1103 with built in antennas is a great performer with out help. The design is pretty solid as is. I have compared it in stock form to other radios with an external loop and the DE 1103 holds it own. Cheers

Topic: 6277 Message: 6291

gmcjet pilot,
Here's a bit from over on the Kaito 1103 group (still applies to the Degen 1103: QUOTE: Re: Question About 1103 (message number 337)

I've had the 1103 and the 1102 for several years - I recall that there was at one time, early in this group and "programmable" mode that changed that external antenna input so that as an example if you plugged an external antenna in while the radio was in the AM mode, it would disconnect the internal antenna and function off that external hookup.

Mine operates that way and it is very evident when tuning in DX AM stations. While I did that mod I also did the program mod that allowed for using those frequencies just above the normal AM band, because I was interested in the listening to 160 meters in SSB.

Don /Unquote

Having said that, HERE is the programming 'hack' I mentioned that allows tuning below 530khz and above 1700khz AND bypasses the AM ferrite antenna for the external antennna. This information is from http://www.rosestone.me.uk/Degen/VLF.txt :

Quote: It is possible to tune the 1103 receivers below 100kHz, and to disconnect the internal ferrite rod antenna on MW + LW, by using this simple procedure with the SCAN function.

Normally, a 'scan' will remain within the selected band, with the tuning scale showing progress through the band. If you start a scan from outside a band, the scan will become 'trapped' within the next band that is reached. However, starting between 1 & 9kHz above any band upper edge and scanning down, will bypass the 'band' system, and will not switch to the ferrite rod in the range 1710 - 100kHz. The tuning will also continue below 100kHz.

So, select 1711 by direct entry:
[1] [7] [1] [1] [band+/AM]
and scan down: hold [BAND-] for 2 seconds.
As soon as the frequency is below 1710kHz you can stop the scan and use the rotary control, or you can let the scan continue below 100kHz.
The antenna is now switched for the telescopic or external antenna.
I suggest you tune it down to zero and store this in preset 0, or store 99kHz in preset 99. Also store any frequencies for which you wish to use the external antenna input. You can store any frequency with the [SSB] mode 'on' for CW reception.
Once you tune above 1710 again, the system will revert to the normal tuning range with the ferrite rod for MW + LW. (my note: this is NOT

true IF you start the radio using the preset memory channel and tune with the thumbwheel. IF you punch in a direct entry frequency it reverts back to the ferrite rod however. If I start in memory 99 channel and start tuning with the jogwheel tuning (thumbwheel) I can tune ALL the way to 30Mhz non-stop.)
==========
There has been a suggestion that you must start the scan at 21951kHz because that was the designer's employee number, but that story is apocryphal!
==========
There is another procedure at http://mods.radioscanner.ru/degen/mod29/ for tuning above 30MHz (AM), possibly up to 35 - 37MHz depending on hardware alignment. UNQUOTE.

So, it IS possible to use the Degen/Kaito 1103's with a loop antenna for LW and MW modes. With a simple software hack performed once and stored, you can tune below or above the 'listed or advertised' ranges of the radio. By the way, there is a spreadsheet out there that shows all 22 (10 hidden) bands the 1103 radio will cover. I also have the Degen 1102, the hack worked on very early models, and the software was apparently changed. But the 1103's definitely will use this hack. Both are remarkable radios.
Regards,
Bill
KC9CS

6292. Re: Want to learn about shielded vs. unshielded and tuned vs untuned loop merits

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-02 13:42:22 UTC
From: cank13cat
Topic: 6272 Message: 6292

My main goal has been to minimize noise from the usual sources in any residential environment, such as my own computer, neighbors' TVs, etc. Being in an apartment without a patio or balcony I'm limited to indoor antennas (tho' occasionally on weekends and holidays I'll sneak a random wire up a nearby tree).

I tried a few unshielded wire loops in my apartment, all variations of the many-turns-of-wire loops. All were noisier than the internal ferrite loopsticks in my portables and offered no advantages for my purposes.

On a lark I tried a shielded loop. Hadn't planned to but rescued a long hank of TV coaxial cable the maintenance crew were disposing of after remodeling another apartment. I just followed the basic outlines in Joe Carr's "Receiving Antenna Handbook" and seen elsewhere all around the web. However, being lazy I first tried it without hooking up the air-core tuning cap I'd planned to cannibalize from an old radio.

Darn thing worked! Moderately directional on MW, but mostly it really reduces the local noise problem without merely sacrificing signal strength. It even works reasonably well on HF up to 10 MHz with strong signals, enough so that I can use it for Radio New Zealand on 9765 in the wee hours. I use it fairly routinely for listening to broadcasts in the 49m band at night, where signals are typically strong. Much less noise than my portables on a whip. Above 10 MHz it's pretty much deaf.

The coax is just wrapped around a closet door as a sort of frame. The coax was long enough for two complete wraps around the outer edge of the door, with a 12" gap between the ends. The door can be opened or closed (partway) to make it somewhat directional. On MW it's reasonably directional below around 1200 kHz. Above there the directional advantage is mostly confined to reduction of locally generated noise, which varies depending on time of day and how many neighbors are watching TV. As you can imagine the racket kicked up by hundreds of TVs in my building and the nearby complex was fierce throughout Super Bowl Sunday, with that distinctive buzz emitted by TVs, DVD players, converter boxes, etc. Not even the shielded loop could help there!

Eventually I'll rig up a more refined version with the air core tuning cap. But this untuned version works surprisingly well as-is.

If you have ever only used email to subscribe and access this Yahoogroup, then it might be slightly complicated and an unsub/re-sub may be the easiest way. However, if you have ever used the web to access this group (say, to download from the Files area), do this:

1. Go to the group's main webpage, which you can find at the bottom of every group email:
2. Click on "My Groups" which is a couple inches down from the upper right corner. You may need to "login" at this point.

3. Click on "My Email Preferences" which is about 3 inches down from the upper right.

4. Click on "Add/Remove Email Address". Again, it may check for your password again.

5. Click on "Add Another".

Andy

Hey Bill - SOunds like you are having fun. I've had great results w/ a multi-turn loop on BCB w/ the 1103. Even barefoot it is an amazing performer. BTW, it still throws me for a 'loop' (sorry:) to see a 9 callsign from Florida.

Hi
Since I joined the group I have poured over the Files page and gathered quite a bit of info. My goal is for a loop antenna for SWLing from 3-30 meg. Everything I have built has not come up to the promised results. I am in the process of constructing another loop, but I want something that is not so lousy on higher bands. Does anyone have any ideas what I should do? All the best Curtis

What type of receiver are you using? How are you coupling to the radio?
What type of signals are you expecting to receive?
What higher bands?
Indoor loop? Outdoor loop?

Just trying to find out why "it does not work" means. I'm not the expert but this is how I go about trying to resolve problems during my day job.

I am using a Palstar 30A. There is nothing wrong with the radio as far as I can tell. I also have and older Yaesu FRG 7 recently checked out and claimed it was in fine shape. I made a small 24" loop and was not impressed by the performance. I dont know if I am in a poor area for reception, but things were alot better before I moved. I have tried a longwire and the noise was to much. I placed a tuner in line, placed a balun in line, changed to a dipole. My former neighbor used a loop on 20 daily. He talked me into trying a loop. I am in the process of setting up a loop for contact on 20 as well. But some how I am not so sure this is going to work with such poor success of the receiving loop. I reall enjoy following SWL broadcast and CW on 20 but with the situation now I am not sure it can be over come. Curtis

It will probably take two tuned loops to cover that range .... You can gain some low end range on a loop that will tune to 30Mhz by placing an equal or slightly smaller value cap in parallel with the existing tuning cap (A larger value cap could be used to go lower but your ranges won't overlap) Or you can put two variables in parallel which is slightly better because it doesn't spoil the Q as much

Another option would be to make a multi turn loop (maybe 2 or 3 turns) and switch turns in and out.. For example 2 turns for the low band and one turn for the upper ... again you have the same p[oblem with lower Q as the number of turns rise but it doesn't seem to be as bad as with the parallel cap option .... Extra turns and/or capacitance also affect the nulls but a loop's null isn't all that great at above 30 or 40 meters anyway

May I suggest in your case to give up the loop idea and put up an active E-probe or active whip antenna as high and in the clear as you can get it, preferably on the roof above all the surrounding noise. If you can lay a chicken wire ground screen around it (10X10 square) and tie it to the shield of the coax, it would help in preventing near field noise from entering the probe from below.

Active whips are very broad banded. Usually from 100 kHz to 30 MHz and should satisfy your need.

Hi Curtis,

When I was in the big city for several years in an apartment situation I
used such a loop for SWL. I tried a number of different arrangements.

The criteria I required:

must be tuned to provide maximum Q and thus selectivity and noise reduction.
must be directional ... e.g. have a sharp null to reduce local noise.
must be able to be tuned from a small distance as I wanted to locate the
antenna out on the balcony.

Here's how it works:

I formed a loop with light copper tubing .. perhaps 1/4 in. The diameter
of the loop was approx. 2.5 to 3 ft. (not critical)
I supported the loop on wood sticks everything held together with
electrical tie wraps (great invention)
I fed the loop with balanced feed line (TV twin lead)

I used if from about 4 mhz tropical band up to 15mhz ... you should be able
to tune higher if you keep the feed line length short.

Jim

6304. SWL Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-05 19:09:32 UTC
From: brian russell
Topic: 6296 Message: 6304

Curtis,
I myself used a 138ft perimeter diamond shape horizontal wire loop at 25ft
for over 25 years as an SWL, covering all bands 40m - 10m, it worked
exceptionally well.
Since 1985 I have used it on transmit with equal success.
Below 40m I just disconnect one side of the twin feeder and use it as a long wire.
Look on the Internet for ' Skywires ' or NVIS antennas.
72, Brian, G0NSL-QRP.

Thanks for all the response. I have been busy this morning checking out all the work I had done. Thinking I had created a nice piece of work. It was little more than junk. Last week I ordered a Autek Analyst. It came this morning and quickly it showed that the cap I was using was bad. It was a new piece but not working. I took it apart and discovered that the insulation used to hold the shaft was bad. I cannot explain why. It looks fine, but when you remove it the Autek says it is ok. If you reinsert it, it fails the test. Shorted. I have worked with many caps and bought used ones at ham fests but I have never seen anything like this. So in the trash it goes. No way I could put all back together and make it work. I wrapped a piece of cardboard around the shaft and it worked and tested fine. It would have been a waste of time to make it work. I purchased another with a lower capacitance. It seems to not matter, because the radio now jumps to life on the AM BCB. I am surprised. I guess you don't need all the extra capacitance. I will replace it with a larger size. I am still not happy with the performance on the SW bands. I guess I am going to use some of the ideas you guy have given to see if I can get a better signal on SW. I plan on making a butterfly cap this weekend for a 20 meter loop. Two other questions Does the diameter of the tubing make a difference in bandwidth? If you use wire, is it neccessary to use mutiple turns say for 20 meters. If anyone has ideas on where not to make a
mistake please let me know. Also thanks for the friendly responses from all, as well for the advice. All the best Curtis

Hey George,
I'm glad you got it to work. Sharing these ideas is what this forum is all about. I learned a lot coming here, it's nice to be able to reciprocate. And you're right, it just makes that radio all the more versatile. Being able to connect an external antenna to the MW and LW frequencies brings a LOT of new listening available.

Vintage? I don't know other than to tell you that I've had it about 1 year. Couldn't find a serial number on it, it may be inside the battery compartment but I didnt' want to remove the batteries and then have to reset the clock and such, worried it'd remove my frequency memories.

I read somewhere, sometime, that the ground system in your house is an antenna. So yesterday I hooked a wire to the ground screw on a 115V outlet, and ran the wire into a 9:1 balun, then connected the balun to the antenna jack on the radio via coax. The balun is also used to connect my outside longwire. Well, I got just about the same performance boost as the longwire with just slightly more static, barely detectable.

Worth a try and worth playing around with, but be careful of the power side of the outlet..

Yes,
The diameter does make a difference. Some folks have made HF loops out of 2" diameter copper pipe(!), for transmitting, it does make a difference. For receiving, not so much.

Here's a page with a lot of info:
http://www.qsl.net/mnqrp/Loop/Mag_Loops.htm

Here's a page with a lot of loop links:
http://www.mindspring.com/~loop_antenna/
And another:
http://www.dxzone.com/catalog/Antennas/Loop/

Good luck,
Pappy Hiram

Frank in Boston
Ground is not always ground even if it is from the power company. Things are not always as they seem. I told this also on the Elecraft forum many years ago. When I lived in Florida I could not get a ground. Nearly every place is sand. Not a ground but and insulator. They make glass from it. ... I tried a long wire and so much rf feedback in the shack that it was dangerous. You could not touch certain pieces of equipment. A nasty bite. I placed a tuner in line of different types. T's, L's, modified, no luck. I even placed the tuner outside the shack trying to get the rf out but nothing worked. I went outside and put so many rods of various lengths in the ground thinking I had it fixed. Still, no ground. It was so bad that if someone turned on the faucet at another home you could get shocked. I got and ohm meter and measured the resistance from the white wire to the ground and it was above 20 on the scale. Notice I did not say the black wire that is a hot wire. The white is neutral. When testing it you should read around 5, 6, or7. If not and it is above 10 or 12 ohms you don't have sufficient ground. I am not sure of the correct number, I need to look it up again. To make a long story short the electric company come out and drove metal beams into the ground past the hard pan. It cured the problem and my shack became friendly again. I agree that there is enough wire in your home to make ground but if the power company is deficient in a proper ground you could make a big mistake. Just be careful.

Thanks Pappy

The links are very helpful. I should have done an internet scan but I have been so busy searching books at the library. The eneginnering books I have read through are poor on hf loops, but heavy on loops designed for satelite data used in the 60's. How much of it relates I dont know. When I moved I gave away most of the books I used never thinking I would need them again. Thanks for the links.

I've been getting good results with a homebrewed passive magnetic loop for my Palstar R30C. Assuming the new R30A is pretty similar (I think it has internal 9:1 impedance transformers inline with both antenna inputs), you might give it a try.

It's based on the design written up by Joe Carr in his Receiving Antenna Handbook and repeated in several places online with minor variations. Coaxial cable with an opening in the shield at one point. In my case I looped the coax around a handy closet door! Opening and closing the door makes it somewhat directional.

Most designs call for a tuning capacitor. I was in a hurry to try mine and omitted the air core tuning cap I'd cannibalized from an old radio. Turns out it works fine without the tuning cap from MW through approx. 10 MHz. Could be improved with a tuning cap, but I'm content since it works on the bands I listen to most (1000-1700 kHz on MW at night for skywave; 5000-7000 kHz shortwave). Very quiet, rejects most indoor noise generated by my own appliances and neighbors.

Perfect for my apartment since I can't put up a permanent outdoor antenna. Random wire up a tree gets stronger signals on HF, but with a lot more noise. The loop is quiet enough that I can leave the receiver on all day and not go nuts from the static. Signals that would be S9+10 or +20 on a random wire are S7-S9 on the loop, but with very low noise, so intelligibility is comparable.

I will join the peanut gallery and say, DON'T use of house wiring for an antenna or ground. It is just too easy and cheap (and proper) to install a proper ground rod (in the ground). No sure of the Florida sand situation, but I think there are ways around that.

Using home grounds for antennas is a good way to get dead. 110V AC can kill you. At best I might kind of work may be? It could also fry you radio. Just my opinion. George NC

I am not sure what the ground thing is all about ... If your radio or any other appliance has a 3 prong plug then it is already connected to your power distribution ground. If your radio or other appliance does not have a 3 prong plug then it is not connected to the power distribution ground. Now, if any other appliance you choose to name does not come with a 3 prong power connector I am sure the user does not then attempt to create a second ground .... e.g. goes outside and drives a copper stake into the ground (sounds like Vampire lore) Why then for a radio? Any radio manufacturer that specifies the necessity of 'a good ground' is simply anticipating many users will be using makeshift and inadequate antennas. In my 0pinion such directions borders on irresponsibiltiy.

I read where someone who was transmitting (different than receiving) had RF in the shack. The problem was not the lack of a ground ... the problem was the antenna was of a very inadequate design ..... period. NASA transmits all kinds of data from satellites ... small very small .... and they certainly don't depend on a 'good earth ground'.

Any antenna that requires the radio to have a good ground is not much of an antenna.

George,
The home wiring can also work against you. I was testing a receiving loop at 300kHz attached to the side of our office. We had a precision receiver listening to an NDB beacon at a nearby airport. Every time the air conditioner condenser unit (which was located near the receiving antenna) turned on,the signal from the beacon would drop dramatically. We traced it to the ac wiring to the AC compressor which formed a shorted loop around our receiving loop antenna. Not something you have much control over, but we moved the receiving loop to another office wall, and the problem disappeared.
Regards,
Paul

I have to say I disagree with you completely on this matter. If you think that a three-prong plug is always grounded you are just wrong. The city when confronted with the problem agreed with me immediately. They suspected as much because of all the calls that keep coming in. They just did not know where. When I had the city engineer come out he thought about closing our street down until the next day because of fear of a lawsuit. There was no sure ground when the people in the neighborhood could get shocked at the faucet or washing the car. The system was floating. I would never as the city engineer told me depend completely on the ground in you outlet.
I used the antenna for years and never again had another problem. My antenna was very well built. It stayed up for another 7 years. Quality of construction was not the problem. Your gear manual clearly tell you to use a ground on your rig and it's not for lightening strikes alone. When RF is not properly grounded it will hunt for ground and you could be it. I just happens that my place was the worst of the situation, thankfully they fixed it before something serious happend.

Hi,

If your antenna needs to find ground through your radio then your antenna is not properly designed. Yes, the radios does clearly state the radio should be grounded ... that is the irresponsible statement I mentioned in my first post ... a (C.Y.A.) statement. I have operated with many different rigs home brew and commercial... with different power levels from QRP to QRO all modes ... and never has it been required to run a separate grounding wire to a separate ground stake out in the yard. No use arguing and trading anecdotes hi .... we can simply agree to disagree.

Yes we will have to agree to disagree. I lived it and learned from it. All my problems were solved by the city properly installing a ground system. I never again had an antenna problem or RF in the shack. Used the same TT Omni 6, TT tuner, and same antenna, until a hurricane took it all out. All the neighbors electrical problems cleared up as well. All the best to you anyway.

Yup,
Absolutely right. RF ground is different than the ground in your breaker box. They SHOULD BE SEPARATE. As your engineer said, you can't depend on it, and shouldn't. The house wiring ground is for the house wiring, appliances, microwave ovens, toasters, etc. The newer homes have a GFI (Ground Fault Indicator) somewhere in the house, usually kitchen or bathroom, to protect the homeowners against accidental shorts, like dropping the toaster into a sink full of water. RF ground should be to the cold water pipe, or if that's too far a run, a stake or three in the ground. I had one outside the basement window back East when I was a novice. Bring a heavy wire or braid from the ground stake(s) into the shack area, and ground every piece of equipment to that ground. Some folks use a big copper plate and run SEPARATE ground wires to each item; Transmitter, Receiver, tuner, etc. The sand in Florida is a kind of extreme situation, and the solution was extreme as well. Most people aren't faced with that, and a few stakes in the garden soil should suffice. I currently have a cable going to the cold water line where it enters the house, there is a shutoff valve just outside my window, and I ran a heavy cable to the pipe, shined up the copper, and put a hose clamp on the cable. Connections to RF ground should be short as possible, and the ground should be as close as possible to the Radio equipment.

The wisdom of the ages passed down from my Elmer(s) to me, and then to you. Call it a rule of thumb, call it a 'good practice,' but just do it. Electricity can kill you, so be careful! Follow all the safety rules! Always treat a gun as if it were loaded, even if you "know" it isn't. ALWAYS ALWAYS ALWAYS unplug everything before taking the cover off. Turning the switch off isn't enough. PULL THE PLUG, every time! Your life could depend on it.

When leaving the shack, turn everything off, DISCONNECT the antenna from the radio and connect it to ground. You don't need a direct lightning strike to blow out your rig, a big static discharge could do it too.

Be Safe,

Pappy Hiram

From: challanger13041
Topic: 6320 Message: 6320

HELLO I AM NEW TO THE GROUP AND PLANNING A FERRITE ROD ANTENNA
STRICTLY FOR LF BEACON DXING IN THE 160KC-530KC RANGE.
I WILL BE USING A 125MU ROD.MY QUESTIONS ARE AS FOLLOWS.

1. LITZ WIRE IS PREFERRED FOR THE COIL BUT IS THE INDIVIDUAL STRAND
DIAMETER AND NUMBER OF STRANDS CRITICAL (FOR RECEIVING PURPOSES)?
IF SO I BELIEVE I SHOULD USE APROX. #40 GUAGE.ALSO WHAT BENNEFIT IS
THERE IN HAVING MORE STRANDS RATHER THAN FEWER? AND WHEN INCREASING
THE STRAND COUNT: AT WHAT POINT WILL THERE BE NO FURTHER BENNEFIT?
2. HAVE BEEN CONSULTING WITH OTHER HAMS ABOUT A SHIELD,THEY SAY TO
KEEP THE SHIELD LONGER THAN THE COIL BUT SHORTER THAN THE ROD...
WHAT IS A GOOD RULE OF THUMB...HOW DO YOU DETERMINE THE OPTIMUM LENGTH?
3. WHEN MAKING A SHIELD: I HAVE READ ABOUT MAKING IT LIKE A TROUGH (V
or U SHAPPED)...WHAT ABOUT IF YOU WERE TO USE A METAL TUBE SLIGHTLY
LARGER THAN THE COIL AND ROD DIA. AND SLOT IT ALONG ITS LENGTH (SO
THAT THE ENDS COME CLOSE BUT DO NOT TOUCH/SHORT ?

ALOT OF QUESTIONS!
THANKS VERY MUCH
DAVE

Dear Jim Dunstan:

I'm not going to get into the GROUND WAR's debate, but we disagree.

You said a few things that are off base, begging correction. Your arguments are off point or straw man arguments. I am not trying to convince you, but for the record I'll comment.

> I am not sure what the ground thing is all about .. If your radio
> or any other appliance has a 3 prong plug then it is already
> connected to your power distribution ground.

Most modern radios have isolated internal power supplies from the AC power or are battery powered portables. All my AC powered radios have no POWER ground. The issue we and I'm talking about ANTENNA GROUND by the way and not spacecraft. (I'll get to that)

> I read where someone who was transmitting (different than
> receiving) had RF in the shack. The problem was not the lack
> of a ground ... the problem was the antenna was of a very
> inadequate design ..... period.

This is a blatantly incorrect, a broad statement that has no real relevance and is propaganda. No one is arguing a radio can't "WORK", with out a dedicated ground for power and/or the antenna.

Many antennas are balanced and require no ground. Many radios are not grounded at all, totally isolated from the AC power or utility ground. This is not the issue. The issue is safety and performance, mostly safety of using UTILITIES for antenna ground.

The Ham radio literature, radio and antenna owners manuals all warn against using home wiring for the antenna circuits. I will admit I have tried it. IT IS LAME. There is nothing like a proper direct EARTH ground IMHO. Antenna design books agree.

> e.g. goes outside and drives a copper stake into the
> ground (sounds like Vampire lore)

It is not legend, lore or urban myth, it is real engineering by people who have long past-on, that knew more about radio than I ever will. The importance of a good EARTH ground on HF antenna systems and radio performance and safety is really not in question.

> Any radio manufacturer that specifies the necessity of
> 'a good ground' is simply anticipating many users will be using
> makeshift and inadequate antennas. In my 0pinion

> such directions borders on irresponsibility.

I don't know what to say. WHAT?

NOT ALL ANTENNAS NEED A GROUND, ie balanced antenna designs, dipoles and loops. 'Reciprocity' says good RECEPTION performance means good TRANSMISSION performance and vice a verse by antenna theory (with limits).

From my experience with "classic" random/long wire type antennas, my SNR goes from poor to very good with a proper earth grounding through a transformer/BALUN, just my experience. It has NOTHING to do with local RFI in the shack. It correlates well with technical documents and antenna design by experts, who know more than I do.

> "NASA transmits all kinds of data from satellites ... small very
> small, and they certainly don't depend on a 'good earth ground'"

How do you know what NASA does?

Also understand there are inherent differences from LF/MW/HF and VHF/UHF/Microwave? Also understand the difference of an earth base stations and space craft. Right.

Obviously an airplane or space craft is not grounded to earth but uses the airframe as a ground plane. BASE stations and mobile antenna designs are inherently different. Even the same ANTENNA used as a base station v. mobile may be installed differently and will operate differently. When you can avail yourself to a good Earth Ground for the front end of your radio its almost always a winning idea and worth the effort. Every thing else is 2nd best or make due.

You can install a MOBILE antenna design as a base station, aka NO EARTH GROUND, but why would you if you don't have to. Again UHF/VHF are NOT GROUND BASED (following) signals to start with.

NASA is irreverent, a red herring to the subject, using the house wiring for an antenna ground. It is just a poor idea, dubious at best, may be deadly to your radio or even you.

My opinion leave the home wall socket ground screws alone for certainly crappy performance is more likely than not, IMHO.

The safety issues like lighting strikes and noise issue of using home wiring ground on the RFI side of a radio's front end is not disputable IMHO. It's considered bad form, poor practice.

However I'm not the antenna Nazi. I'm a antenna libertarian, experiment and do what you want, just be careful.

Going on my personal experience a good GROUND (really truly a dedicated earth for the antenna) has made phenomenal difference

in my antenna designs (that needed a ground). The affect on large base rigs or portables is the same, night & day for the better. Some times the difference is nominal but some times spictacular.

You can get into 'circular logic' about 'ground-loops', what is a ground and how to properly ground, but on the RF end of the radio, GROUND is critical for many antenna system designs but not all.

Consider antenna and power grounds are different. Even if your radio's circuites has a common power, chassis and antenna RF ground, having a CLEAN GROUND with the preverbal stake in the EARTH ground is goodness. It sheilds and protects from outside the "shack".

WHY NOT give your self the best possible ground for you antenna?

> "Any antenna that requires the radio to have a good ground is not
> much of an antenna."

Your comment is irrelevant. What is the symbol of ARRL, Association of Radio Relay League?

http://www.arrl.org/news/images/arrl-c2.gif

Dead Sea Scrolls of radio going back to the 30's, 40's and 50's when radio was king, the "art" of antennas, design & analysis show a good EARTH GROUND is key. I mean GOOD. Many grounds are poor. The main reason for not installing a good ground I see is avaibility (appartment or mobile) or lazyness.

There is no need for me to repeat what you can google the topic. Here's a link of basics of ground and radio ("Grounding is key to good reception", is a good article):

http://www.hard-core-dx.com/nordicdx/antenna/ground/index.html

A portable radio with a plastic case and a whip antenna, it's not grounded in ANY WAY! (well its internally ground) Often just introducing a good ground to a portable radio improves the SNR. It's magic! Try it.

Have you made a crystal radio? In the old days all pipes where copper or steel and ground was easier to get. Now its all plastic.

A dipole antenna is not grounded and should not be grounded.

Most mobile antennas, Ex. airplanes are reflected 1/4 wave dipoles (1/2 wave effectively) requiring a ground plan or ground radials. Aircraft NAV antennas (VOR/LOC/GS) are true un-grounded dipoles. Radar is a paraboic microwave antenna.

Repeat an antenna ground is not always needed or called for AT ALL, but when it is, using home wiring is dangerous or not affective.

> Any antenna that requires the radio to have a good ground is not
> much of an antenna.

That is a confusing comment? The antenna is one thing & the radios power or ground is another. The ground can be common. The antenna and radio can have seperate grounds or no ground at all. There is no one common answer to all applications and designs.

NONE of my radios have a POWER GROUND (to the radio circuits, they float)!

All my RX radios are all powered by battery or have internal isolated DC-DC power supplies from AC-DC two prong converters. Large transmitters or TUBE rigs, even if they have AC heaters, even if they have a AC ground plug, are no different, the theory of radio has not changed since Guglielmo Marconi.

KEEP IN MIND the transmitter you are listening to LF, MW, HF is grounded. Don't you think having the TRANSMITTER and RECEIVER being in the same EARTH ground is goodness? Yes

Some military transmissions are sent through earth.

VHF is different and NOT ground/ionishpere based. VHF/UHF are line-O-sight and go through the ionosphere. Antenna EARTH ground is not as much a performance issue.

The ANTENNA SYSTEM and how radio propagation works, the importance of EARTH to the signal is not debatable in my opinion. It is not a myth or some wild idea akin to stakes in the heart of vampires.

This is not a flame just a serious subject safety, than second performance of antennas. We disagree clearly. Just from lightning concerns, outdoor antennas need a dedicated outside earth ground. You can kill your self or burn the house down.

Drive those dedicated GOOD ground stakes deep for best clean safe performance!

Cheers George

Advice is free and worth every penny.

At the risk of stirring a hornet's nest, I'm a former safety inspector. Over the years I've seen a lot of incorrectly wired homes, industrial facilities and machines: no grounds attached to the grounding socket on the outlets; cheater grounds, with the neutral and ground bonded inside the building; reversed polarity between hot and neutral; etc.

The worst is reversed hot and ground. Rarely happens but that's one you really need to watch out for. I encountered it twice in several years of inspections, once in a new construction site, once at a manufacturing facility. Shocked heck outta me both times, literally.

The main reason I avoid using a residential electrical system for anything other than providing power is the noise. My two receivers that do have ground provisions only pick up more noise from the usual well-intended advice to use the ground screw on an outlet, switch or junction box as a ground, or the water pipes.

The quietest reception I get on MW is with a homebrewed shielded magnetic loop and no separate ground. It's a compromise but works in my RFI-rich urban area.

There are inexpensive outlet testers (2 to 4 dollars) on the market
that simply plug in and some lights tell you if you have a bad ground,
reversed hot and neutral etc.
A little money very well spent.

Alas, won't tell if ground is connected to neutral. You would have to physically inspect outlet and wiring to uncover this condition.

Hi Gary,

Yes, I have a couple ... one in each tool box. I use them all the
time. As the other person suggested, you never can tell about power
outlets ... I am always checking and finding faults hi hi.

Hi,

Do you mean the ground and neutral connected together in the outlet box
!!! They are of course connected to the same place in the main panel
(except for a few jurisdictions that have altered the code making it
necessary that they have separate and isolated buses.

But only in the main panel. I have seen conversions from 2 wire systems where the bond was made at the outlet. Picky point but normally a code violation.

For my portable radios, Sangean ATS-909 & Grundig G6 - 1) I run on batteries and 2) I leave the radios floating above earth. When using a 9:1 balun I will ground the high impedance side to earth on one side when using a single wire as an antenna lead. For portable operations, I tie one antenna lead to the ground side of the low impedance end of the balun. I leave the low impedance (50 Ohm?) side floating with respect to the radio. I don't like using the ground lug on the AC for safety and noise reasons. Safety has been discussed by others. From a noise perspective, I have too many things including a noisy transformer in my backyard to want to use electrical ground.

Hi,

I believe the person who has electrical background as an inspector mentioned he had a home brew shielded magnetic loop for MW. I would also appreciate a description of his loop. Years ago I experimented with shielded and unshielded magnetic loops and found no detectable difference between them. Since then I have done quite a bit of experimentation and reading on the subject and the key points I have found are as follows:

A 'magnetic loop' is simply a 'small' loop that is much less than a 1/2 wavelength in circumference ... often 1/10 wavelength and less. The magnetic loop can be 'tuned' or 'untuned' and has the characteristic that the current in the loop goes in the same direction at all points along it's circumference. It is also less responsive to the electrical component of the electromagnetic waves ... thus the name 'magnetic' loop. It is generally accepted that most local RF interference is more electrical than magnetic thus the small 'magnetic' loop less susceptible to this RFI than a random wire, dipole, or whip antenna. in a sense, the ferrite antenna in MW receivers are already 'magnetic' loops.

The magnetic loop has a radiation or receiving pattern that is roughly a figure eight with broad loops and narrow, sharp nulls (the nulls of the magnetic loop are perpendicular to the plane of the loop). I find that the most useful aspect of this pattern are the nulls ... which can be rotated towards the most offending RFI source ... thus further reducing 'noise'. It has been my experience that the tuned magnetic loop performs better than the untuned variety ... all things being equal. However this may be due to my inability to provide proper amplification to the unit.

The magnetic loop can be made even more immune to local RFI by placing a special shield around it. The theory is that the shield acts mostly against the electrical component than the magnetic component which further increases its noise reduction characteristic. The shield must be symmetrical with a narrow break. The feed point is usually 180 degrees across from the break.

As I mentioned above I have not been able to detect the difference between comparable loops shielded vs unshielded. However others swear by them. I feel that the added demands of shield construction is not really rewarded in added performance.

Jim

I see at hamfest an on eBay dozens of books on antennas. I have the ARRL Antenna Handbook, but are all the Copendiums worth the time to collect? I've looked through a couple of volumes, and seen a few antennas that might be something differnt but, generally alot of what I have seem is in the ARRL Handbook and Antenna Handbook. Has anyone read through all of them or a major portion? I thought about just collectin them for reference, and change my mind every time. I noticed one the other day that was almost all dipoles, longwires, etc.
I plan on going to the hamfest in Charlotte, NC in a few weeks. Really it is in Concord, and I know there will be masses of books. The best hamfest I've ever been to is Shelby on Labor Day. But I am wondering if they are worth getting. The Lord knows I dont have a need for another anything to do with radio. But sometime I think about it.

That was probably my post. I'd tried various "bare" wire multi-turn loops. They were just as noisy as a random wire or vertical in my area. The shielded loop solved that specific problem - an omnipresent cloud of white noise from RFI/EMI in my semi-urban area.

My homebrewed shielded loop is based on the various designs described and illustrated in Joe Carr's classic "Receiving Antennas Handbook." Since it's copyrighted I can't reproduce it here.

Fortunately, many folks arrived at similar schemes over the years and a very similar design can easily be found on dozens of websites by Googling "magnetic loop antenna" or "shielded magnetic loop antenna" - either seems to work, just varies the number of hits slightly.

The main differences I see now are more exotic loops illustrated online by hobbyists. Some of 'em are using copper or other metal tubing and making some designs that, at least externally, resemble the popular Wellbrook loops.

I simply used what I had handy: a hank of old TV coaxial cable, roughly 25'-30', scavenged from the dumpster after the maintenance in my apartment complex redid a vacant apartment and had new cable installed. I hadn't planned on building a loop, but the coax reminded me of something I'd seen in Carr's manual years earlier.

Mine's not pretty but it works just as described on other sites. The surprise was that it also works on HF below 10 MHz. I hadn't expected it to work at all above MW freqs.

Keep in mind that it's a compromise intended to fill a specific niche: a low noise indoor antenna for a receiver left to "static" pretty much 24/7. (I'm a pirate radio fan and since these transmissions adhere to no schedule, the only practical way to catch this eclectic entertainment is by dedicating a radio to that purpose.)

There's no practical way for me to put up a permanent outdoor antenna at my apartment complex (long story short, been there, done that, proved repeatedly that it ain't practical). And, frankly, I wasn't enjoying HF listening much because of the cloud of RFI that's inescapable in my semi-urban environment. I wanted an antenna that would permit strong signals but cut ambient noise down to a tolerable level so I could simply leave the receiver on 24/7 while listening for oddball signals.

The shielded loop cuts ambient noise to only S1-S2 on the frequencies I monitor most often. I can leave the receiver on all day and not go nuts from the noise. But signals reported at S5-S9 levels by other

DXers are still clearly audible at only S1-S3 on my receiver.

The downside is that I can't hear signals that others report at S1-S3 levels. But it's worth the compromise in order to be able to enjoy the radio more by leaving it on all day. In my environment a higher gain antenna would mean putting up with S7-S9 noise all day. No thanks. And using the attenuation switch doesn't accomplish the same thing as using a lower noise antenna.

This ugly loop has helped me catch hundreds of oddball signals during the past year: pirate radio from the US (including one claiming to be using only 50 milliwatts of power), Canada and even Europe; Brazilian outbanders using CBs modified to work on HF (during the wee hours in the US they can be heard chanting, goofing around, playing music and just cutting up and having fun on 7000 LSB); Gulf Coast fishermen chattering with their wives and families.

And it gets great skywave reception on MW after dark, especially between 1000-1700 kHz. It's just directional enough to screen out the local KRLD on 1080 so I can pick up other stations in the background; and to pick up that great jazz and other music on XEEP 1060 with minimal interference from WLNO; and classical on 1660 from KXTR in Kansas City rather than the tiresome sports talk from more local stations on 1660.

If you have space for an outdoor antenna - any outdoor antenna, even a random wire or CB vertical - you'll get better reception on HF. Even a passive shielded magnetic loop outdoors would beat my rig. But if you're in a very noisy urban or semi-urban environment and there is no practical means to put up a permanent outdoor antenna, it's a good compromise. And my design is nothing special - you can find a dozen variations illustrated online.

6332. Use of Varactor diode in tuning loop?

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-11 15:25:18 UTC
From: David Feldman
Topic: 6332 Message: 6332

Lookg to rework my receive loop antenna so it is tuned to receive frequency remotely. I've looked at several circuit designs that employ varactor diode with DC bias adjustment. One concern I have is the prospect that RF voltage in the loop unfavorably affects bias point of the diode or even drives the diode to conduction or reverse breakdown. Specifically, my loop diameter is 40 inches and I have a couple of AM BC stations nearby (1 and 5 miles away, up to 10 kW).

Comments?

Thanks,

Dave

That can be a problem, and the overall solution may be that you'll need to accomplish the remote tuning with a motor-driven variable capacitor instead of varactor diodes. If you look at my 40m transmitting loop:

http://www.home.earthlink.net/~christrask/Paper012.html

you can replace the dual variable with a more appropriate dual 365pF variable and scale down the physical size of the transformers to the ones I used in the varactor-tuned receiving loop:

http://www.home.earthlink.net/~christrask/Paper011.html

I've been experimenting for the past few days with a similar arrangement for a manually-tuned indoor receiving loop.

In my varactor-tuned loop, I found that there was a high degree of immunity from nearby BCB AM stations, and I found no harmonics even from a 50kW station that's less than 10 miles away. That one sometimes shows up on my 'scope leads when making 10mV/div measurements, so I was a bit surprised when it did not cause problems with the varactor-tuned loop.

Jim Dunstan:
Nice right up on E and M loops or Electromagnetic and Magnetic and shielded and unshielded loops. A little google I found this site and a great detailed write up. Go figure. I started to go though it. A little technical but there is something to that Shielding. I would have thought it counter productive but nay!

Bottom line is the shield is part of the antenna. It also does not necessarily make it less subject to E noise or separate it from the M signal. Interesting. It does have a use but the design of the loop and shield must be right or the results can add noise, even force the feed line into being part of the antenna. I gather done right it does have real advantages but by how much or little is debatable. Of course there are different shielded loop designs, with different pros and cons. Didn't know.

Here is the main shielded loop page:

http://www.w8ji.com/magnetic_receiving_loops.htm

These are some direct links referenced in hypertext in the above page:

http://www.w8ji.com/loop_text.htm
http://www.w8ji.com/skindepth.htm
http://www.w8ji.com/coaxial%
20currents/coaxial_line_and_shielded_wires.htm

Very nice. I want to make my own Mag loop. Shielded or not, yet to be decided.

Cheers

Hi again,

Yes, the shield does become part of the antenna. the reason for the break in the shield is to allow the antenna currents on the shield to travel on the inside of the shield material as well as the outside .... given the 'skin effect' at RF. The loop inside the shield acts like a pickup loop. It may be because of this ... eg the RF connection between the shield and the inside loop is primarily due to induction rather than capacitive coupling (electric field energy is primarily coupled capacitively) ... don't quote me on this ... it is just my thought on the subject. The symmetry of the loop depends on the quality of the shield construction. There may be noise reduction .... from close in E radiation. The side opposite the break is also grounded ... providing a further path for E charges.

I have not seen many MW multi turn loops with shielding. It seems they are more common with single turn loops in the HF spectrum. Even in the HF spectrum the majority of the loops are unshielded and constructed of large rigid material ... especially if they are to be used for transmitting as well as reception.

I have had the opportunity to examine the construction of commercial direction finding loops and observed the shield is of a very large diameter approx. 3 in. with the inside loop carefully centered along the inside thus maintaining maximum distance from the shield. This would keep the capacitive coupling to a minimum and provide a very loose magnetic coupling .... the result being maximum shielding from local interference and maximum definition of the loop radiation pattern ... primarily the sharpness of the

null ... the key characteristic for determining direction. It is also interesting that the loops are not tuned .... but then they are not dxing ... but taking bearings on relatively close beacons. I believe tuning can affect the reception pattern ... the degree of which is negligible under normal circumstances ... but can make the null a little fuzzy for direction finding purposes.

Jim

I think I'm missing something. The shield is grounded right? So how does any signal impinged and travelling on the shield (inside or outside part of the shield) make it into the radio? I just don't get past that point mentally.

Second problem I have is: if the coax's shield were not broken somewhere, how could RF signal energy make it onto the center conductor that does go to the radio's RF input stages with respect to that ground.

My mental picture is the break(s) allow admission of the transmitted energy onto the sensing coil.

In otherwords this question: take any antenna / any design. Build a conductive shield around it that completely encloses that antenna, and ground it. Does the antenna pick up anything?

Too simplistic? Wholey incorrect?
Sam

The incident EM wavefront induces a current on the two shield halves,
and when the plane of the antenna is parallel with the direction of the EM
wavefront these two currents will be of equal magnitude opposite phase,
provided they are sufficiently far enough apart. At the common connection
of the two shields at the bottom the net current is zero. However, at the
gap the circuit is open and the currents then flow around the end of the gap
and onto the inner surface. When the shield is greater than a certain
thickness (usually 10-20 skin depths, depending on who you're talking to),
these two currents on the opposite shield surfaces are independent. The
current flowing on the inner shield surface induces a current on the inner
conductor by way of TEM coupling.

There's a very good discussion of this in:

Carobbi, C.F.M., L. M. Millanta, L. Chiosi, "The High-Frequency Behavior
of the Shield in the Magnetic-Field Probes," 2000 IEEE International
Symposium on Electro-Magnetic Compatibility, pp. 35-40.

>>loop.

I think I'm missing something. The shield is grounded right? So how does any signal impinged and travelling on the shield (inside or outside part of the shield) make it into the radio? I just don't get past that point mentally.

Second problem I have is: if the coax's shield were not broken somewhere, how could RF signal energy make it onto the center conductor that does go to the radio's RF input stages with respect to that ground.

My mental picture is the break(s) allow admission of the transmitted energy onto the sensing coil.

In otherwords this question: take any antenna / any design. Build a conductive shield around it that completely encloses that antenna, and ground it. Does the antenna pick up anything?

Too simplistic? Wholey incorrect?

Sam

6339. How to use small loops for AM DX'ing with portable radios

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-11 19:27:51 UTC
From: gmcjetpilot
Topic: 6339 Message: 6339

The traditional method of coupling an external passive loop and a radios internal loop-stick is the "T" position, where the Loop antenna is leg of "T", aimed at the station (in plane with the loop) and the radio back or long top edge is at right angles. This puts the windings on both loops in-line.

Portable radio loop-sticks are usually along the top-back of the radio, at least the ones I have. Some times they are top-front or along the bottom.

This gives portables the best reception off back or front of the radio. The ends of the radio are usually the null ends, not ideal for reception since this puts the null end of the loop-stick facing the station. So the "T" puts the loops in line at the station.

QUESTION?

I FOUND THAT PUTTING THE LOOP RIGHT NEXT TO THE RADIO, IN PARALLEL WITH THE BACK OF THE RADIO UP AGAINST THE LOOP, WITH THE EXTERNAL LOOP POINTING AT THE STATION, STILL WORKS WELL ?!?!

WHY DOES THIS WORK?

With the radio standing up so the radios internal loop-stick is closest to loop, more or less near the middle of the external loop gives good gain, almost as good or better than the traditional "T" orientation. Even though the flux lines are at right angles the close proximity makes them couple. I have a good idea where the loop stick coil coil starts and stops. The best results are when the loop-stick coil is at the edge of the external loop either to the inside or out side.

TWO OR THREE LOOPS BETTER THAN ONE?
My three loop antennas:

http://img525.imageshack.us/img525/7522/slide3copymh0.jpg

Using two passive loops can be used to get more gain but putting the loops in series or even side by side.

Using one loop for gain and another to null out a conflicting station or noise with the second loop can be useful. Point the second loop at the offending station and using the tuning capacitor to null the signal out.

The article below is good:

Hi Sam,

I am no expert on the subject ... but this is how I see it. If you form some metal tubing in a complete circle .... 2 in tubing in a loop say 3 ft in diameter for example ... and place a second loop around the inside center of the first loop you will have received antenna currents on the outside of the first loop and nothing around the inside of the first loop and no antenna currents induced into the second loop. The reason is that RF is conducted on the surface of the copper material and does not penetrate through the material .... what is referred to as skin effect.

The second step is to cut a small chunk out of the first loop leaving a gap of an inch or less. The second loop inside is left intact. What now happens is that some or all of the current now flows around the outside ... then to the inside via the opening at the gap ... and then around the inside back to the gap and then continues the rest of the way around the outside of the first loop. As a consequence antenna current is induced into the internal second loop.

The radio equipment is usually connected to the second internal loop element at a position directly opposite the position of the gap. In order to get access to the internal loop the first loop/shield is opened 180 degrees away from the gap. The access point is usually made with some kind of shield material ... It could be another copper tube carrying a balanced feed line. If coax is going to be used as the feed line then some effort has to be made to convert the balanced load of the loop to the unbalanced coax feed line. It is very important that the mechanical arrangement be symmetrical so the currents remain symmetrical in relation to the access point and the gap. The consequence of putting a shielded coupling at the feed point is that the outside of the first loop/shield is grounded 180 deg across from the gap.

Such small loops respond differentially to electromagnetic waves that are generated close to the loop which consist mostly of electric fields. The electric fields induce charges on the outside of the loop which are grounded to some degree at the feed point before they in turn induce further magnetic currents. This is I believe the reason for calling the first loop a shield.

So, to make your point ... if there was no gap ... there would indeed be no signal. Even though the outside of loop is grounded ... at the feed point .. there is uninterrupted antenna current flowing around the outside and inside of the loop/shield and around the inside loop (connected to the radio) as a consequence of induction.

Jim

Yes the shield is part of the antenna. I think your observation or what you read that shielding does not add a lot of value is for one reason, there are 15 ways to do a shield loop poorly. If not done just right it will make it worse. It is not complicated just requires attention to detail. The articles I listed show some of the does and don'ts and gotchas.

6344. 1923 Popular Radio magazine articles

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-13 14:36:17 UTC
From: tenorman1952
Topic: 6344 Message: 6344

I sat for the tests and was licensed as an amateur radio operator this past October 2008. I joined the local club and began attending meetings. There I met an older gentleman, Grant, age 93, who is my new best friend. ;-) He lives just a few blocks from my house, I discovered, and due to his poor night vision (he can drive during the day) I have begun driving him to the club meetings.

Grant's body may be failing, but his mind is still sharp as a tack. When Grant speaks, everyone should shut up and listen. And those that know him do.

Last week he dropped four tiny circuit boards in my hand, the smallest about 1" square, the largest about 1.5" x 2". "Do you know what you have there? That's a 40 meter Single Side Band receiver. I just need to finish the case for it." And he proceeded to tell me exactly how it worked.

He showed me a magazine he found while looking for something else... a 1923 issue of Popular Radio. He let me borrow it and I scanned a few pages and posted them in a folder here, 1923 Popular Radio Articles. Take a look.

I did not press down hard when scanning, so there are a few out of focus spots, but you can still read it easily. I was afraid of breaking the spine of the magazine, and the pages were somewhat brittle. I only scanned a few pages for this reason.

The magazine was very well written, questions from readers section, various articles, how-tos, etc. Lots of schematics. What a piece of history!

Of course, Grant is a walking, talking book of ham history and radio knowledge himself.

You meet some great people in ham radio. I want to be just like Grant when I grow up.

Anyway, you may enjoy looking at the few scanned pages.

Congratulations, Paul, on your "promotion" to the amateur ranks.

Those old magazine articles are terrific. I wish we had on-line access
to them all. Back issues from that era are selling for 20 bucks apiece
on EBay:

http://cgi.ebay.ca/ws/eBayISAPI.dll?ViewItem&item=200275707328&indexURL=\
#ebayphotohosting
<http://cgi.ebay.ca/ws/eBayISAPI.dll?ViewItem&item=200275707328&indexURL\
=#ebayphotohosting>

Content of Pop Radio seems to be on a much higher technical level than
"Radio News" a Gernsback "pop'tronics" magazine of the early 20th
century:

http://www.magazineart.org/main.php/v/technical/radionews/
<http://www.magazineart.org/main.php/v/technical/radionews/>

Not necessarily .... Yes that is in fact true for the coax shielded loop (And some others not madde from coax). Technically it's a balanced loop because as you noted the coax shield (braid) is actually the receiving element .... The better the balance the better the nulls and the better the rejection of nearby noise sources placed in the null

But take the case of the ferrite loopstick mounted in a 'U' shaped trough of aluminum, here the shield truly is a shield and not the receiving element .... These are generally most useful for direction finding and RF leakage measuring but can work as receive antennas

Interesting, I was always thinking or focused on the signal and
gain and not the nulls, which clearly has use in rejecting noise
and Dir Finding. Loop-stick in aluminum trough...neat, DF in deed.
Cheers George

Local noise rejection is the main advantage to my homebrewed passive loop made from coaxial cable. The nulls aren't nearly as sharp as a typical AM MW portable's internal ferrite loopstick. But it's enough to minimize local interference and aid in skywave reception for the roughly 1000 kHz-10 MHz range. It's cut way back on the "cloud" of ambient white noise typical of my semi-urban neighborhood too, especially during peak TV watching hours when my outdoor random wire picked up mostly buzz and hash.

I think you are referring to the reference to the 'U' shape aluminium used with a ferrite loop which may act as a shield against close electric fields. I believe the reason it may work with the small ferrite loop is that the loop is very small and the magnetic field very concentrated .... whereas a single or multiple turn loop 27" in diameter would have a very much enlarged field making shielding much less effective. I may be wrong ... I have never tried that and never read of others trying it. Perhaps you are on to something.

In any event cutting the slot would not be necessary as antenna currents on the circular 'U' channel would already be on all surfaces ... unlike the situation if the wheel was a circular metal tube instead of a channel.

Jim, VE3CI

You could use a two piece ferrite core that fits over the
rim to make a transformer that couples the circulating
current in the rim into a feed line. No cut needed in the
rim, and the electric field current picked up by the
capacitance of the rim can be grounded with a single
connection from the rim to ground without much effecting the
magnetic coupled signal that induces the circulating current.

Now, if you make the loop out of tubing and a coupling to
short it, you can thread a one piece toroid (with the output
winding already on) over the pipe before soldering the
shorting coupling in place.

Hello, brains!

I have been wondering, if a grounded metal-sheet "shield" near on the other side of a ferrite loop could make the loop directive from only the "open"-side?

This has been my question for a very long time, but I have never tested it to see, if it would work...

Of course it would be very easy to test by putting a grounded copper or aluminium sheet behind (or forward) a transistor radio equipped with a ferrite rod antenna on a turning base... I just never "remembered" to do it! Too many interesting things coming and going!

What do you think? Worth testing?

73 and good one-direction DXing!

Aimo

Hello Aimo
IMHO that will be of no use, because the ferrite bar loop uses the magnetic part of the electro-magnetic wave, then an electrostatic screen has no effect on the magnetic field, (I think so).
¿More ideas from the group?
Good DX
Jose

Yes this is common with Direction Finding gear. In fact a loop stick in a metal u-shaped channel or trough has been done. A loop stick receives off the sides and the ends are nulls, right. A "U" shaped channel could block signals somewhat from 270 degrees. However the way that U-Channel works is you use the ends or nulls to look for min signal, where the station is.

Do you have an offending near station that is interfering with another station you want to listen to? I have that problem. I have a 50KW station on 850khz 5 miles to the east. To get Colorado +1000 miles to the west on the same freq is about impossible even at night. Thankfully at night the local power house clear channel AM BCB station goes direction N-S, so their strength goes way down. I doubt there is much I could do, except try some kind of uni-direction antenna (LOOP with a shield). The good news is if the station is 10Kz or more off I have no problem. At night I can get two stations at 850Khz one N-E and one S-SW. The LOOP antenna is a must. I have a radio with good selectivity and filters to narrow the band width, which helps.

You could try a shield with a flat plate, but radio waves bounce around and can get to your antenna jumping around your flat shield. I am no expert but you can play with it. Clearly you can change the gain in that direction. As I said you would want a U-shaped channel to make it more uni-directional and try to get a signal off the one side? I am no expert on the math and technical issues, but try it.

Here are some things I have tried that do work as "shields".

Say you have a portable radio with a loop stick. Say you have two passive 9" loops (tunable) and you are inductively coupling the loops to the radios internal loop stick. You can use one loop to boost a signal and another to null a signal from a different direction.

You null by pointing at the offending signal and trying to tune a notch or min gain, or you can turn the "shield" loop 90 degrees and face the side to the station and move the radio relative to the loop so the signal is muted.

The other way is to make a freq trap as well with a tunable capacitor and coil which is inserted into the feed line of an antenna as a filter or trap from certain freqs. You can actually put one or two or three traps at different freqs to trap or filter out freqs you don't want. In my case where both stations are 850khz

and are 180 degrees apart and one is powerful and far and one is
powerful and really near, there is not much I can do about getting
that distant station. Working distant stations N and S and are not
on the exact same freq is easy.

Cheers

Thanks, guys!

Now I am wondering, if a strongly magnetized iron or steel sheet would do the trick to minimize or totally nullify the magnetic part of the signal? This will probably show my perfect ignorance about these things, but just a thought anyway...

Hello Aimo
IMHO that will be of no use, because the ferrite bar loop uses the
magnetic part of the electro-magnetic wave, then an electrostatic
screen has no effect on the magnetic field, (I think so).
¿More ideas from the group?

Thank you, Jose'!

Does GROUNDING of the "Shield" mean nothing?
Won't the magnetic waves also go to earth/ground?
And, if a steel or iron sheet will be strongly magnetized,
and if the "shield" would cover the ferrite rod loop
from all other directions, but a very narrow desired
direction? In theory or in practice...?

Thanks for a very interesting answer,"gmcjetpilot"!

A "Mini-Flag Loop", which has a resistor towards one direction,
is a very effective means also to minimize interference from the
opposite direction. I have to continue tests with one as well as the
Mini K9AY as soon as the windy season will be over. I namely had to
postpone these tests because of very strong winds, that made my DX
One Professional MK II fall down, and take the other antenna off from
my Rotator.

I have noticed, that building, fixing, connecting and testing is about
all I'm doing here... Listening for DX takes less time and perhaps
interest, too.

One day soon I'm going to test things, which you suggested, I hope...

Re the recent question about a shield plane on one side of a loop antenna: some years back "Palomar Engineers" (USA) offered a product called "Channel Scrubber" which seemed to be similar. However the use was applied to a small portable SW radio which laid on a platform; the shield plane actually shielded the extended whip antenna on the small radio. (BTW, this item has apparently sunk into history like a foot-print in the ocean; i found no listings on a Google search.) There is a review of the product in a WRTH from maybe 10-12 years back - guessing at the date. So at least there may be some potential to the idea.

Aimo
If you put a magnetized steel plate (= a magnet) near your ferrite antenna, probably you get the ferrite saturated because the strong CONTINUOUS magnetic field from the magnet, making the ferrite less able to collect the ALTERNATE magnetic field from the wave.
I dont think that grounding the plate change anything.

Thank you for your opinion, Jose!

Have you tested these things in practice?
Another stupid idea:
A "wall-shield" of several equal ferrite-
antennae as the one used in reception.
All connected to earth, only.
I have over 40 ferrit-bars to build a rather
large "shield" of them...
About a magnetized metal-shield, why
should it be so near the receiving ferrite?
Why not so far, that it could not "saturate"?

About grounding: If I connect an antenna
only to earth, what happens? Will the
signal, any signal, go to ground? Or will
the antenna turn to be a transmission-
antenna, transmitting all received signals
to the space? Now we have a problem of
signals, that pass through earth. No shield
can protect us from those unwanted-ones
near or on the same frequency, we want
to listen to...
So, an army of "traps" will then be one of
the best methods to deal with interfering
transmissions from any direction...?

When using my TEN-TEC RX340 DSP I have
many other possibilities too, like SAM, USB,
LSB, ISB,CW,CWI,FM,PBT,Notch Filter,
over 50 IF widths and many directive antennae,
many add-on-devices, like preselectors, audio-
manipulators etc, but I also want to test my 3
SONYs and many other receivers, now and then.

Thank you for your patience, Jose1

Best Regards from Aimo

hi Jim,

Yes, I have used a resonant loop .... actually a quad ... a driven loop with a reflector loop. Easy and cheap to construct and very effective. I don't have one at the moment and don't have the plans ... I have seen them on the internet ... I am sure a 15 minute internet search will give you directions and dimensions. The dimensions you need are loop circumference, reflector circumference, distance between driven and reflector elements, and length of matching stub if you use one.

Hi,

I took a quick look in my handy Antenna Book and see they have a description of a 2 element loop antenna for 144 mhz. (cubical quad). It is simplicity itself. It uses 1" x 1" lumber for the frame. The elements are made of # 8 aluminium wire that is self supporting with a single 1" frame member.

The driven element is 83 in. (formed into a square) and the reflector is 5% longer or 87 in. The driven element leaves an opening for the feed point ... a small piece of plastic can be used there and it is fed directly with 50 ohm coax. the driven element is closed and spaced somewhere between .15 to .25 wavelength distance (12.5" to 20.75") from the driven element. They recommend adjusting the spacing for the best SWR ... as it has little effect on antenna gain.

The resulting antenna has forward gain and is quite broadband. If you just want a single loop then simply forget the reflector.

Jim, VE3CI

Jim,
For compactness especially out portable see the Moxon Loop page
at www.cebik.com , there is a ' stand alone ' calculator for dimensions.
I made mine from 8mm copper central heating tubing with just
a central 16mm dia PVC boom.
Works well with 2.5 watts from a FT-290 Mk1.

Hi Brian,

Are you referring to a 2 mtr moxon ??? Interesting ... actually I have
been thinking of making a moxon for 20 mtrs. actually a 2 el yagi with the
ends bent towards each other. yes, I have read the info on the moxon by
cebik. thanks

That sounds familiar. I don't recall the Palomar model, but Joe Carr had a couple of designs for shielded loops as "portable helper" antennas, to improve the signal to noise ratio and minimize fluttering fades and QRM from two stations at roughly equal signal levels. These were in the small loops section of his Receiving Antenna Handbook.

I've seen similar designs online, mostly using boxes or squares made from thin sheets of metal, or even aluminum foil. Some involve a turntable, others use aluminum foil on a sheet of foamcare, with the portable sitting on the foamcore inside the perimeter formed by the foil loop. One of the coolest expedient variations I've seen involves using a loose tail of aluminum foil and a book to slide the foil tail around as a rough capacitor for tuning!

6374. two meter loop design needed

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-02-24 18:52:37 UTC
From: brian russell
Topic: 6364 Message: 6374

Hello Jim,
Nice to hear from you.
Yes my Moxon loop is a 2m version, the 16mm PVC boom has a
' T ' piece in the center to slip on a 16mm PVC mast made of 2 x 1m
lengths, though I did fit a timber insert inside the tube to add strength
without any real weight increase, by making one core longer than 1m
that facilitated the jointing method.
The mast sections go down my rucksack corner and the Moxon hangs
on the back like a snowshoe hi!
At the spacing point of the elements a piece of 10mm dia Delrin is used,
the ends being reduced to a ' tap in ' fit to the 8mm copper tubing.
I have thought of an ' add on ' director, just another piece of 16mm
PVC tube with a rod element, or better still using two telescopic whip
antennas from a BC set, that way they would fold flat down the
extra boom piece for carrying.
Regards,

This is my opinion after owning a Passport book and looking at
WRTH's web site. I am no expert but this is my opinion.

For Freq and time alone I find the web is free and fairly good.

There are few web sites that you can type in a search or ask for
all the radio stations on air or specific freqs or locations.

There are several online freq search engines,

I have used it. It's pretty good.
http://www.naswa.net/swlguide/

"Monitoring times" (available on the news stand) is pretty
good and here is an online list
http://www.grove-ent.com/mttopHF.html
http://www.monitoringtimes.com/html/reference_library.html

A list of many links to other SW radio freq lists
http://www.ac6v.com/swl.htm#GSWL

For MW in the US "Radio Locator" is great.
www.radio-locator.com/

For MW AM Clear channel (50KW'ers)
http://www.ac6v.com/clearam.htm

WRTH I'll say I am least familiar with but in my opinion from
what I have read and their web site they appear to be serious
about pure freq/time data base. They have online updates I think.
Not sure if WRTH has all the reviews and other info or just a dry
data base? Not a put down I don't know. I like Passport because
its more than just data.

I love my Passport book. I bought a 2006 version of passport last
year on Amazon "used". Obviously not up to date. With shipping it
was so cheap why not, a few bucks. However I love the reviews of
radios and antennas, of which 2006 had reviews of my two SW radios,
which was a pleasant surprise and a review of an antenna I lust
after (Wellbrook). The book is about 2/3rds or 3/4th info and the
rest freq data. They don't divide by language, but Freq, County
and Time. That may have changed, I have 2006 right.

Passport has good basics informational stuff. Since I was getting
back into radios after a long absences when I was a teenager 25 yrs
ago. It also has profiles of big SW radio stations around the
world. The radio and antenna reviews are really great. I have a
TenTec RX320D and Degen/Kaito 1103. I was pleased to see they

where passport picks or well rated in their respective categories.

Passports Freq/Time/Location data base looks very complete down to contact info for the station. It has nice bar graphs. The graphs are grouped in Freq ranges than by country/location and than the bars show the time on the air.

The be honest I rarely use my book. My MODE OF OPERATION is to scan and find stations. Than I figure out what station it is. Of course not speaking Spanish, Italian, french, German, Russian and even Arabia, impedes my deciphering of the station, but in general I can figure out where it comes from.

Also my radio is a PC/Computer based radio. I down loaded ILG data base into the radio. Use to be free or they sold the data base part off, but I have a data base about 6 mo old. Data base is great because you just click and it goes into the radio.

Mostly I'll turn to the online radio data base, or the data base in my radio or saved station Freqs. I found the on line data bases are not correct or complete all the time (or I am using them incorrectly). I'll put in a freq that I know is on the air and it does not come up. Or it will come up with a station that is clearly not the one I have (language).

If you go the other direction and target a station than the books will help you. However the art of receiving distant stations is a bit of challenge any way. I tend to use my spectrum scan and look for signal I can get at that time.

Try amazon and check the prices, you will be surprised what last years Passport goes for, cheap. Even older data will give you a clue of what is going on, plus has cool reviews and suggestions.

Than you can go to the web and see if the station has a web site with latest freq/time schedule. SW times and freq change by seasons, but tend to use the same freqs.

Cheers

PS language is not always a key to location.

There are remote repeaters in the US. RCI (radio Canada Int'l) transmits many foreign language programs from North America. Some are foreign radio programs in English, which is interesting getting the news about China or Netherlands, which is going through issues with Islam and muslim immigrants as many parts of Europe are. Doha!

Here is a good site with world radio stations. These folks shoot some big power. http://radiostationworld.com/

Most SW stations in the US are religion stations
http://radiostationworld.com/Locations/United_States_of_America/shortwave.asp

Of course you have to time stations in the US and Canada:
US Time: 5,000, 10,000, 15,000, 20,000 Khz

3330 kHz (3 kW)
7335 kHz (10 kW) changed to 7850 kHz as of 01 JAN 2009.
14670 kHz (3 kW

BBC is SW in North America is dead. They stopped to focus on
satellite and cable TV for NA. They still have SW in South America
and Africa, Asia. I get BBC on digital cable TV. Top Gear is one
of my favorite shows. The news from other countries is always
interesting to filter and contrast to what you hear from our
networks. Here are some more links to radio sites:

Latest edition of this schedule version, including AM, FM, satellite
and webcasts with hotlinks to station sites and audio, is at:

From: gmcjetpilot
Topic: 6377 Message: 6380

This is my opinion after owning a Passport book and looking at
WRTH's web site. I am no expert but this is my opinion.

For Freq and time alone I find the web is free and fairly good.

There are few web sites that you can type in a search or ask for
all the radio stations on air or specific freqs or locations.

There are several online freq search engines,

I have used it. It's pretty good.
http://www.naswa.net/swlguide/

"Monitoring times" (available on the news stand) is pretty
good and here is an online list
http://www.grove-ent.com/mttopHF.html
http://www.monitoringtimes.com/html/reference_library.html

A list of many links to other SW radio freq lists
http://www.ac6v.com/swl.htm#GSWL

For MW in the US "Radio Locator" is great.
www.radio-locator.com/

For MW AM Clear channel (50KW'ers)
http://www.ac6v.com/clearam.htm

WRTH I'll say I am least familiar with but in my opinion from
what I have read and their web site they appear to be serious
about pure freq/time data base. They have online updates I think.
Not sure if WRTH has all the reviews and other info or just a dry
data base? Not a put down I don't know. I like Passport because
its more than just data.

I love my Passport book. I bought a 2006 version of passport last

I blew tha dust off the passport guide and actually its pretty amazing with info especially if you are new to SW. I said it is only 1/2 data, really it is about 80% data and it does have english only station section. Like I said at amazon, you can get last years for cheap. It will have pretty good data. Cheers

6382. Router RFI - Solved Big Time

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-06 18:13:52 UTC
From: q97323a
Topic: 6382 Message: 6382

I posted this elsewhere but might be of interest here:

This is quite an amazing story IMHO.

I bought a laptop for Xams to be used upstairs & a DLink Wireless Router (D615) to connect it to my main computer in my radio shack where the cable modem is located. As soon as the Router was plugged in I knew I was in trouble RFI wise.

After many hours of troubleshooting, experimenting & changing locations of the Router, nothing worked. Using my portable Eton E5 I determined that the stock 5VDC Power Supply was the culprit by conducting & amplifying digital hash from the Router Box into the house wiring & then into my radios - untenable. I managed to find an old, heavy 5VDC Zip Drive Power Supply that worked fine & quietly - obvously it had good filtering components. Unfortunately, it is rated
at only 1 Amp (whereas the stock PS is 2.5 Amps) causing it to run quite warm - not good.

I contacted DLink Canada with my problem & requested that they find me a quiet PS with the proper rating. Of course they had never heard of such a problem & initially I was dismissed; however, I persisted in a polite manner & the file was passed to their Toronto engineering staff who took it over.

Well, to make a long story short, yesterday at my home on Vancouver Island on Canada's west coast, I hosted 1 Dlink Tech Rep from Toronto & 2 DLink Electronic Engineers directly from Taiwan to confirm my problem. These guys flew half way around the world to specifically address my Wireless Router RFI problem & flew home last night - extraordinary effort on DLink's part & simply amazing to me.

When I plugged in their stock PS with my Kenwood R1000 tuned to the 17Mhz Band, they winced. One engineer was DLink's PS expert & brought a bunch of different units to test. He confirmed my diagnosis that the stock PS was injecting square waves into the house wiring. His PS's all worked well so good PSs are available out there.

While this type of RFI problem will not affect 99.9% of their customers as there are so few SW Listeners anymore, they now know of radio enthusiasts' RFI problems with their products. They took a qenuine interest in my situation & went well beyond the normal service call on a component that cost $50!! So DLink spent a ton of money to give me a replacement PS & I'm very grateful.

Hopefully, we have made some headway here in our constant battle with RFI producing compnents. At least this company now recognizes this fact.

Cheers

Am i correct that the old noisy supply was just a diode
unregulated supply, or is there some kind of switching supply in it?
Were you able to keep it, to tear it apart and see?
It amazes me that the manufacturer actually responded to you!
Usually, once they have your money and the product works, it's goodbye!

Hue:

I still have the original PS that is light weight & enclosed in a very small housing. Compared to the PSs that are properly filtered, it is about 1/4 of the size & weight. That should be a clue in itself. Not being an electronics guy, if I broke it apart I wouldn't know what I was looking at.

It is obvious that this diminuative type of PS is not adequate for filtering RFI; however, the radio enthusiast world is so small that the vast majority of their customer base would never experience this problem.

I never found my WiFI caused any RFI for me, but the two biggest offenders of RFI was my computers Scanner/Printer and wireless mouse. The scanner/printer fix is unplug it, when not in use. The wireless mouse is OK when not moved, and only affects some of the higher HF freqs.

My issue is I use a Ten Tex RX320D, which if a PC based radio, so I have to have the computer gear nearby. However I do have a Palm PDA that I can use to control the RX320D, which is cool, but

Flat screen monitors/TV's make some atroucious local RFI.

I got the noise issue solved by using and outdoor antenna with shielded coaxial, balun and good outdoor GROUND (in the ground).

The the Ten Tex RX320D just a BOX, all the control (except on/off) is by software. The BOX is as far away from the computer as I can get with an 8' serial cable that connects the radio and computer.

I took a portable HF SW radio and went around the house and used it for a RFI noise detector. Almost everything makes some noies right next to it. The issue is how far it spews the noise.

I know where noise is coming from, and the best solution was the outdoor antenna away from the house and the coaxial feed, balun (random wire 400ohm to 50ohm) and a good ground with copper in the dirt.

The remote tune active magnetic loop I am making will go on a poll, rotor and outside the house.

>> "there some kind of switching supply in it?"

Switching power supplies are the WORSE and can be at switching at very undesirable Freqs.

No wall wart is perfect but you want linear types, which tend to be physically bigger, heaver and a more little expensive are better. Linear wall wart pwr spplies where the standard and typical. Now you see a lot of switching AC/DC converters.

The RX320D runs on a wall wart, linear and has a CHOKE or one of those Ferrite beads on the wire from the power supply to device. You see those ferrite beads or chokes on computer wires also, that plastic blister you see on wires. You can buy them and snap them on a power wire, usually you loop the wire though twice. You can buy them cheap and they keep stray noise from being picked up and fed down the power wire.

Cheers

It is a switching power supply, and the Zip drive power supply you tried is a linear regulator supply.

That is how I would expect it to be. Switching supplies have lots of fast switching, so there must be careful filtering and shielding to prevent RFI from escaping. In a linear supply, the fastest switching is the current pulse of the filter capacitor charging at 120Hz.

The PS that the DLink Engineer left for me is large & of the same size & weight of my old Zip Drive PS - the main difference is that it is rated at 2.5 Amps & therefore runs much cooler than the Zip PS that was rated at 1 Amp.

That make me feel better.

gmc:

Four of my 5 antennas - PAR EF-SWL, 'Snake in the Grass', DIY 1 Meter multi-turn Loop on a rotator & a vertical 20' Slinky are outside. The first 3 are 30' from my house & fed with properly shielded coax & grounding.

Even they could not mitigate the RFI being injected into my house wiring. I guess that battery power is really the only way to go....

I've had the same problem with those little 5v (cheap, poorly designed) switching power supplies but found using them with a UPS keeps them from radiating back into the power likes ... Problem is they don't use any input filtering and you really need filters on the input as well as the output ... A good UPS provides some isolation and filtering

The reason you got engineers is I suspect they already know they have a problem with compliance of whatever the Canadian equivelent of the FCC is and don't want a complaint to them triggering a recall of thousands of units and/or a hefty fine

The problem here is companies usually submit a in-house power supply made by their R&D department to pass compliance, then they farm it out to some ChiCom factory and frankly, the ChiComs don't give a whit and will cut corners (like leaving out input filters) to maximize their profit (Or just to make a profit because they underbid to steal the job from an honest company) They know agencies like the FCC won't do a random check for compliance like they should, so they get away with this and if they do get caught it comes back on the company that contracted to them and not back to them

If you think food and paint in children's toys are the only places they cheat, think again ... I have little faith in anything coming from China and believe they are slowly bleeding countries dry in exchange for "Trinkets and Beads" .. Crap that doesn't last more than a

couple of years and gets pitched into a landfill ... Anyone foolish enough to believe you can practice Free Trade with Communists needs to look up the meaning of Communist again

5 antennas I am jealous. I can barely get one up with out the HOA police sending me a letter.

Have you thought of a Wellbrook ALA1530? Those mag loops can not perform miracles but they have been the solution to many peoples RFI issues, with reports of people getting great drops in Noise by 3 or more on the S-meter, while getting the same signal, which means a GREAT S/N ratio improvement and really the KEY to this game.

Yes, RFI is a devil. I was so frustrated and it took a lot of effort to solve mine. I was going to give up but finanly hit upon the solution for my problem. No need to get into detail because every situation is different, but it was the antenna design and going outside, balun, coax and ground ground in the ground (not some other thing like some try using the home wiring ground). Please no 'ground' wars guys.

I am nervous, things are good noise wise for me, but they are making the two lane road out side my development wider and putting in some high power lines along it. I am in the front of the development and may be 1000' or slightly more to the road and power lines? We shall see or hear I mean.

I have a second antenna I am making, an active magnetic remote tune (varactor) loop, like a wellbrook. There is nothing they (antenna nazis) can say, its a 1M dia loop (like a satellite dish) and it will be on a rotor. Actually re-reading the covenant, the rule is 1M max antenna UNLESS it is needed for reception? Humm. May be I should put the random wire up again. The problem is the lot is small and surrounded by green areas on two sides with nice trees. Unfortunately the trees don't belong to me even though they appear to be in my back yard. I would like to use one for a wire but they got on me about it after a year. It is going back up in the spring with the leaves. They will not see it.

There are nice things about being in a planned HOA community but there is some real drags, like paying dues and rules that cramp my antenna style.

Any way good luck. GMC

gmc:

Yes, I've always lusted after the Wellbrook; however, its high price has been a deterent for me. I recently built a DIY 1 Meter Loop in which I stuffed as many turns of 3-conductor TV Rotator Wire into a 10 foot plastic tube that I bent into a hoop. I estimate that there is about 250' of continous wire inside with the way that I soldered the ends of the conductors.

I managed to snag the last TV Antenna Rotator plus 200' of the 3-conductor wire from our local RS for 60% off. I soldered the 2 ends of the rotator wire of the loop to 50' of buried coax into my shack thru an old MFJ-956 Antenna Tuner & MFJ-959C Tuner/Preamplifier. So I have a nice Loop that performs very well from LW up to 17 Mhz. I've received a lot of NDBs that are completely lost in noise or missing due to weak signals on my other wire antennas.

My Loop may not conform to normal theory or convention, but it does work fairly well. I'm under no illusions that it rivals a Wellbrook, but now that I have a rotator already erected, perhaps a Wellbrook just might be in my future. Either that or I'll tackle a 2 meter Loop project this summer.

At 0200Z (1900 PDT) I'm resently listening a wonderful signal from Radio New Zealand on 15720. My Loop is easily rivalling my PAR EF-SWL here with no RF boost.

I am somewhat lucky as the power cables in front of my house are underground. Generally RFI is tolerable here in the smaller town where I reside.

From: david_medders
Topic: 6393 Message: 6393

I am in need of advice regarding an amateur HF antenna implementation. I have recently moved into a home that is antenna restricted by Home-Owners Association. I have approximately 100 feet of 8-foot tall wood fence -- supported by spaced metal posts -- that seems an ideal location to conceal a loop. I am contemplating an SC-230 tuner mounted in the middle of the fence line, feeding 14 gauge Silky wire, creating either a loop or a folded dipole along the top and bottom of the fence. Based on my limited NEC2 abilities, it appears the folded dipole provides a better NVIS pattern. My questions:

1. Is this a reasonable/good antenna?

2. Loop or folded dipole?

3. How much should the wire be spaced from the fence? The metal posts?

4. What you use to mount the wire on, and space it from, the fence?

Thank you in advance,

David

Hi David,

I understand you have 100' of 8' fence on which you can either form a 116' loop (using the top and bottom rails of the fence) or simply place a 100' dipole along the top of the fence. You plan to feed the antenna (loop or dipole) with an automatic antenna tuner.

First, a rectangular loop 100' x 8' will not be very efficient in terms of the capture area. Mechanically it will be more flexible than a dipole in that you can feed it just bout anywhere along the 100 ft fence .... whereas a dipole along the top of the 100' fence must be fed at the centre. As long as the feed point is not a problem I would go for the dipole along the top of the fence (you didn't mention if the 100' fence is in a straight line ... that is what I am assuming) since the bottom of a loop would be a few inches from ground.

As far as the metal posts ... not to worrry ... as they are perpendicular to the field of the dipole. As far as mechanical fastening of the wire to the fence ... I would go to the rural hardware store and purchase standard fittings (quite cheap) used in electrical fencing.

I now have a question ... why are mentioning a folded dipole? A 8' x 100' loop is not a folded dipole. If you wanted to construct a folded dipole you would have to use some kind of ladder line or 300 ohm twin lead.

Hi Gents,

I'm new to the list. I have been a mostly inactive ham (tech) until I went to a local antique radio show and got inspired to repair my Grandfather's SW receiver. It's up and running, but not finished. So in the mean time, my condo restricts how large an antenna I can put in the attic since the attic is small. But at least there is attic access.

I'm interested in making a loop antenna. I have a Vector Network Analyzer that is great for looking at antenna's and revealing swr, impedance, bandwidth etc. What I am finding is that it's not easy to get a loop any where near 50 ohms. Granted, I'm a total rookie. But I'd like to pick up a design that I can make easily, test and tune, for any band, as long as it works. It seems from a few rough experiments the feed point design is critical. This was true a few years ago when I was helping a bit to design BlueTooth antennas. I hope some of that scales to 2-160 meter designs.

I'm close to buying a Tak-tenna. But at heart I'm a builder and want to spend time tweaking and tuning on my own. I don't really have a band yet that I can call home, I can barely get WWV on 5mhz. I am a decent fabricator and have good soldering skills.

I have looked at all of the photos in that section. I'm wondering if there are any more pics regarding the feed point on successful designs. I'm partial to not using any matching components(caps/inductors) in the design, if that is even possible.

At some point I'll get a transmitter. But for now I just have the SW receiver.

Thanks for your time,

Mike

Hi Mike,

Before any useful response can be made I (we) need to have more
information. What will be the approximate size of the loop ... eg will it
be made of wire and approximately the circumference of the attic ... or are
you thinking a magnetic loop ... e.g. less than 1/10 of a wavelength ... eg
for HF it might be 3ft in diameter. Since it is going to be used for SW
listening and Amateur transmissions later we can start as a receiving
antenna only.

Assuming you are going to make it out of wire and as large as the circumference of the attic will allow ... you might as well design it to be a resonant 1 wavelength at an Amateur band ... so you can start to use it for that purpose once you get around to getting a transceiver in operation. The formula to determine the resonant size of a full size loop is 1005/F(in mhz) = FT As a result a 20m loop will be approx. 70ft in circumference and 40m 140ft in circumference. If you can make it 140ft go for it ...

The impedance of a full size loop is approximately 100 ohms ... not a bad match for coax .... for transmitting ... and just fine for receiving. Hook it to your receiver and it will work just great. The impedance match for reception is not critical ...However, if you are going to transmit then it is a different story and there are other considerations in order to achieve antenna/feed line efficiency and acceptible load for your transmitter.

Hi Mike,

Yes, it is the ARRL Antenna Handbook .... it is in the 13th edition .... I have older editions but this particular project (2m 2 el. Quad) is only in this edition. The electrical information is in all the editions ... the difference is in this edition it actually shows a simple construction project ... just uses wood for the spreaders and the boom. The wire is self supporting soft aluminium. But it is really pretty simple and all it does is show a line drawing of what it might look like ... if you need it, I can scan it for you.

Jim,

I should pick something, but since I cannot get anything right now in the hams bands, then I suppose smaller is better for right now. I am more interested in proving the concept of how the feed point influences the antenna at ham frequencies. It's easy to scale up to something that will fill the attic for the receiver after I get some feed point experience. But for now I need the antenna to be small just for prototyping purposes. Maybe you know of a ham band from near 60mhz that my receiver could tune to when I get a prototype made?

Here is a great example of a small loop type antenna:
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=18393

I'll do the math you have provided for a full wavelength loop and see if it might fit in the attic. 70ft might be the limit however using rough math.

Oh, one other issue. The antique receiver, an ACR-175 from RCA only has the old clips on the back for antenna and ground, no coax connection. Will making a short cable that adapts to my receiver and the RG8 that I have work ok in terms of impedance match, etc?

Not sure about the concept ... "the feed point influences the antenna" ....
usually it is the antenna, its construction and location, that influences
the feed point ... eg its impedance.

>Here is a great example of a small loop type antenna:
><http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=18393>http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=18393

The antenna you are referring to is actually a special arrangement of a 2
element yagi with the ends of the elements bent in towards each other, the
MOXON, It does look like a loop. It is a very interesting antenna with a
very high front to back ratio with a reasonable amount of gain. When all
aspects are adjusted properly it represents an almost perfect match to 50
ohm coax. This is true for only 1 small frequency band. As soon as you
move the frequency all performance characteristics are off.

Your receiver antenna input is already configured for a balanced
input. Forget the coax and simply feed the loop in the attic with balanced
feed line ... like TV twinlead ... then all you do is connect the 2 leads
to the 2 connectors on the radio. Usually there were 3 connections ....
sometimes called antenna 1, and antenna 2, and ground.

or A, B, and GND. If you are using single random wire antenna then
connect the wire to A and then connect B to ground. If you have a balanced
feed line then Connect the 2 wires to A and B with no connection to
ground .... that is no connection from either A or B to the ground connection.

When using a large wire loop in the attic .... you won't have to worry about matching impedance. The input impedance of whatever size you end up will be all over the map as you go across the MW and SW frequencies. For reception that is okay ... once you want to send RF up to the loop you can go back to the drawing board.

The Moxon sure looks like a folded Yagi now that you mention it. It still qualifies as a condo loop for my uses.

In my notes from years ago when I was learning to make Bluetooth antennas, the steps for making one were 1) Adjust the feed point to match the impedance, 2) Adjust the element's length, width, positions etc for tuning to frequency. That's how I remember doing it. Now granted, you cannot have a 50 ohm match without some amount of antenna already at least roughed out. But I do remember that the feed point adjusted the impedance so radically that it had to come first. This was for PIFA (Planar Inverted F Antenna) antennas. Not sure is that will apply to any other type.

Mike

Mike, since you are looking for a receiving antenna your main objective should be an antenna configuration providing largest possible "capture area". It is not that important to provide feed with "matching impedance" to your receiver. However, a "real" Earth ground is very helpful.

I hear you. But I can tell you that a matched and tuned antenna also has higher gain. So it will matter on receive as well as transmit, on a given band. At least it shows up that way with Bluetooth. I suspect the band is not important. But I feel that my concept is. Gain is gain weather it's receiving or transmitting.

I am not looking for an easy way out. I want a matched and tuned antenna even for just a receiver. Although I could very well pick up a transmitter this year.

This is a very interesting research for me. I sure don't mind the investigative time spent.

> At 0200Z (1900 PDT) I'm recently listening a wonderful signal from Radio New Zealand on 15720. My Loop is easily rivalling my PAR EF-SWL here with no RF boost.

Yea I love getting RNZ from the east Coast. My goal is to get their DRM signal. I get their SW when the weather is right. DRM needs a
min signal threshold or its zip.

The night I listened to RNZ SW, I was amused at the content. It a
combo of stuff I never have heard or haven't listen to in a LONG
TIME:

-BBC radio drama mysteries from the 1930's (I think)
-Music Frank Sinatra (before my time but great music)
-News, interesting to hear other news
-More eclectic music I never heard or from the 60's, 70's?

For awhile I thought my radio was in a time machine, ha ha.

Any one wants to listen to RNZ they have streaming audio web
cast. They also have a big antenna array you can see on google
earth.

Good Luck,

PS - Lived in Seattle for 15 years, worked for Boeing as an Engineer and did flight instruction out of Seattle Boeing Field and flew
freight, charters, corporate pilot and Horizon air. Spent many
a lovely day in Victoria. The wife and I would take the ferry from
Seattle (old and slow and high speed). Great fun.
from Seattle. Had noon tea at the Empress.

6408. Re: Fence-mounted loop

Yahoo group: loopantennas (2008 — 2012)

Topic: 6393 Message: 6408

I feel for you with the HOA. I have that issue as well.

You did not mention this but I would run a random wire, about 75' or as long as you can on the top on electric fence on standoffs. The standoffs are for electric fences and they can be in neutral colors and not very obvious. They also come in bright orange. Not sure how high the metal post stick up above the fence if at all.

The wire (could be 20AWG white or black stranded) goes to a 9:1 balun, local ground with a coaxial feed to the house. It's just a random wire. Nothing fancy but its my go to antenna and is about as new as dirt.

What you are doing sounds interesting.

Not sure about the loop scenario. I assume the metal fence post are 8 feet apart? You could make magnetic square loop up to 8' by 8' out of wire or copper pipe. You would tune it with an Air Cap remote tuned with a stepper motor? Kind of fancy. It could be a TX antenna of course as well as RX. You could tune a RX only loop with electronics and a variator.

A loop is going to be directional along the fence line.

If you google the web for loops you can see what you can adapt. I'm not on my main computer and don't have the saved links for ones that might hang off a fence. Again plastic electric fence stand offs. I assume you could make a multi turn radial loop? Still it would be limited to two directions down the fence line and I guess sky waves.

Folded Dipole with the wire MID fence, sounds OK but not sure about the metal fence posts bisecting it. Clearly you want some space. I would put the folded dipole all above the fence like the random wire. However if you are using say ladder line its going to be way more visible floating above the fence on stand offs than a single skinny wire (random wire).

This does not have anything to do with the fence. But if they (HOA) let people have satellite dishes this might apply.

What I and another Gent where talking about is the Wellbrook loop. I am making 1 meter diameter active magnetic loop and it will go on a poll and rotor just above the roof line. I am going to DARE my HOA to say something. It is RX only.

Based on the rules satellite dishes up to 1 meter are allowed.
Why would a hoop not be allowed. It meets the rule.

The nice thing about the wellbrook is you don't tune it and it
is directional, but it does not have such deep nulls it is deaf
on the sides. So it could be fixed somewhat. The down side is if
you have some boomer AM BCB station it can bleed. That is the
worst thing I have ever heard and it is only if you are close
and point the loop at the station.

Wellbrook makes a model that detunes the MW band so this is not an
issue, but you lose the bottom freqs. By the time you buy it, ship
it and buying all the things you need to install, including the
coaxial you are looking at close $400 or more. Base price with shipping is about $280 US
(ala1530).

You could hang that wellbrook on the fence but what a waste. I
would put it on a poll in the yard it is pretty invisible and
its a pretty aluminum hulu hoop. You could put it in the attic.

I just would not hang a nice loop like the wellbrook on the fence,
but it would work. It would be expensive and not the ideal way
to mount it.

If you are going to use a 100 foot fence I would think you want
to use its length, which would lead to wire antennas, random,
dipoles, zipps, beverage. I would just try to go as high as you
can on-top of the fence aways from the metal posts.

What about your yard, Just on a poll put the loop. You can make a
loop look fairly innocuous, like some pop art. If the neighbors
complain out a nylon net on it and call it a dream catcher! ha ha

Have fun playing. George

Mike;

Understood about matching. Thing is, SWL means anything from 1.8 mHz to 30 mHz. No single antenna "cut-to-length" antenna will match across that wide a frequency spread. So now you get into design considerations & tricks.... Off-center fed dipole vs. closed-loop dipole with termination resistor (T2FD) vs. multi-element/multi-length dipole vs tuned loops vs untuned loops vs electrically short active verticals and dipoles.

If you like to stick with resonance as your guiding design principle, I'd suggest looking at the Chris Trask' paper in the files section "Varactor Tuned Loop Antenna.pdf". It's a good starting point. There's great info in the files section and on the web w/ the help of Google.

BTW - I live in a high RF area - lots of AM, FM & TV w/in 10 miles. Tuned antennas (loops in my case) help since they, by nature, act as bandpass filters.

Thoughts?

Mark

Hi,
As a confirmed ' looper ' for many years using basically a W0MHS
' Skywire ' for 40 - 10m QRP operation I have never had any problems
with feeding via 120 ohm flat twin, no ATU required on 40, just a touch of
tweaking on the other bands.
As for impededance, I seem to recall in W8JK's book ' Antennas ' there
is a graph showing the impedance of a closed loop antenna and it has the
75 ohm point coinciding with 0.75 wavelength.
72, Brian, G0NSL-QRP.

Sounds like my situation (apartment, wooden fence between complexes). I'm considering rigging up a discrete ewe, flag or pennant antenna using the wooden fence as a support. Based on feedback from other MW and HF DXers using these antennas in similar situations (urban and suburban RFI-rich areas), this may do the trick for me.

At the moment my main antenna is a homebrewed passive indoor shielded loop (approx. 3' wide, 7' high). Not bad, but could stand to be a bit quieter and might also work in a variation of the design rigged up on the same wooden fence.

Hi Brian,

I see you mention using 120 ohm balanced feed line (computer cable). I wonder if you could let us know about your experience using this cable for antenna feed. Hve you tried using it at any power levels beyond 5 watts qrp? cable companies used to make low impedance rf balanced line (75 ohm) ... both a low power and high power version. However it has been dropped from the product lines. I used to use it all the time to feed both dipoles and loops. In a pinch I have been using speaker wire and zip cord ... but performance of these products is questionable at RF .... it certainly works ... but I have never seen specs at HF.

For example ... when operating portable at my daughter's house I have a light dipole and feed line made from #16 speaker wire. It works vy well at 20 watts ... but as mentioned I am not sure how efficient it is as the low impedance feed line.

Thanks.

Jim, VE3CI

I sure don't expect one antenna to do it all. Right now I need to know how well these various compact designs actually tune and match. For now it's perfectly fine to have a narrow band antenna, as long as I get some gain out of it. I have a lousy long random wire snaking up through and into the attic to compare my efforts to.

I'm finding encouragement from an article that gives very specific dimensions for loops in the several ghz range. So right now I'm seeing how it scales to 5-60mhz. I'm using all of the loop docs I have found on the various sites, Joe Carr's books and with empiracle testing on the analyzer, for guidance in making the various test loops. The goal being a tuned, broadband loop.

I've found that with a 1ghz loop that adding a solid square reflector of the same size behind the loop, that it can be brought into tune. It's a bit sensitive to tune, but it shows me the concept is possible. I just used a square reflector as it was laying in the junk box.

In one of the articles I have found, it shows great benefit from a parasitic loop added to the same interior plane as the main loop, that the loop becomes very well matched and is tunable without any components. The bandwidth looked to be 2-3 times wider than the same loop without a parasitic element. I roughly proved this one day on the bench. This same article tests a Rhombic pair of loops wired in parallel to make a serious improvement in bandwidth.

Is there a decent loop laying around that I could purchase from someone here in San Jose so I could test a known good loop?

I've read about the varactor in one of Joe Carr's books. What a neat idea. I'll look more into that. But my goal is tuning without components like we use to do years ago. I think the energy transfer to the air is more efficient so the field strength is maximized.

If you want to cover all the SWL bands get an "Evesdropper" antenna. It's a five band trap dipole. It's cut for the shortwave broadcast bands rather than the ham bands although it works well there too. I comes with a twinlead feed -or- a co-ax connector (without the co-ax) and a Zap Trapper lightning protector. I got mine from the AES catalog. All assembled and ready to go. I used one in England in the '60's and am currently using one here in Arkansas. They work great for -receive- only.

6417. Wire dipoles & verticals

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-13 05:02:37 UTC
From: revex540
Topic: 6417 Message: 6417

I have uploaded a pdf file taken from a book by E M Noll, published in 1984. It has construction information on a range of wire dipoles and verticals for the BC & SW bands. It is in the VK7KRW files directory.

Regards
Bob VK7KRW

Jim,
Thank you for the mail, good to hear from you.
When I first erected my 40m full wave loop back in the 1970's it was
fed with 75 ohm TV co-ax, with an electrical 1/4 wave of feedline the SWR
was 1.5 : 1.0.
I always understood the impedance of a closed loop was in the 110 - 120 ohm region
so when some 93 ohm co-ax came my way in the early 1990's I simply swapped the
75 ohm feedline for an identical length of the 93 ohm, SWR went to 1.15 : 1.0.
This stayed in place until around 6 years ago when working a German station on 40m
he told me his 40m loop was fed with 120 ohm flat twin, naturally having never heard
of this cable I queried it, apparently it had a separation between conductors of 4mm.
I hunted around and found that 15 amp rated DC power line had just that, mainly by virtue
of the thicker insulation.
Again I simply swapped the feeder and by trimming the length to 24ft 3 inches it
produced an SWR of 1.0 :1.0 with no ATU in line, lucky ??? most likely hi!
All my operating has been with a Kenwood TS-130V at 5 watts, SSB only,
however the antenna has been used by a friend with his FT-840 at 100 watts
and no problems.
In the UK years ago we could buy 75 ohm flat twin but having single solid
conductors it was hopeless for breaking in the wind, hence I always use
stranded wire for all antenna work.
The present 40m loop is made of 7 x 0.02mm silver plated PTFE covered wire,
scrap from aircraft wiring looms hi!
Regards,
72, Brian, G0NSL-QRP.

Thank you for your emails!

Now I am vey astonished at your policy of
putting prices on certain products.
It seems to me, that you value your R$
almost as high as US $

What might be the corresponding value???

I purchased both the WRTH and Passport
through AMAZON.com.
I paid USD 29.09 for WRTH and 21.59 for
the Passport, both prices post paid!
You know for sure your prices for those
books, R$ 129,00 and R$ 110,00.

Another example: In the USA the price for
Degen DE1103 is from 50 to 85 US$, in Ebay
49.95 US$ + mailing costs. Your price for the
same product is 6 to 8 times higher in plain
numbers of your R$ (How much is the difference of
those two currencies now?)

When you gave me the prices of your
other products, the value of your R$ had
raised too high, at least IMHO, in relation
to the US$...

Either you value the mailing costs very,
very high, or you mix USD and R$ in a very
odd manner...

Conclusion: Your prices are really too high!
It means, that you seem to be too satisfied with
your sales in your own country, and not willing
to be fair with possible foreign customers?

R$ 1500,00 seems to be a very high price, if
the same type of calculation is in effect for
the SONY ICF-2001D / 2010 (almost 30 year
old receiver). I bought one as new in 1985 for
US$ 500.00 in Finland. It is still in very nice
condition.

Love for money seems to raise prices!

Thank you, but nothing more!

Aimo

Hi Brian,

Thanks for the interesting response re: 120 ohm balanced line. Just a note on the 75 ohm line I used to use .... it was manufactured by Belden Cable ... es came in 2 versions ... the low power version was quite small in diameter .... smaller than RG58 by a half. I don't recall if it used solid conductors or not. The high power version was referred to as 72 ohm Kilowatt cable .... it looked a lot like chunky TV twin lead. It certainly used flexible copper of about #16 or #18 gauge.

Later when I worked in Northern Canada and the Arctic I noticed that the Native trappers used small portable SSB transceivers for communications between the village and the trap line cabins. They used low slung dipoles fed with the low power 72 ohm cable. the radios they used had twin antenna posts for connection to this type of cable ... not coax. Now that also was about 20 years ago. I have not seen that cable anymore ... and I assume the updated radios now use coax feed lines to the dipoles.

By the way the SSB transceivers operated on batteries and put out 2 or 3 watts .... somewhere in the 5 mhz range. The dipoles were simply hung in low hanging branches or supported as an inverted Vee ... often no more than 5 mtrs high. The home village would be in the 20 to 50 mile distance. I was amazed at how effective the systems were ... with excellent communications.

Jim, VE3CI

You've piqued my curiosity.
Are you going to be able to build a reflector loop/element that will work at say 6 mHz? Seems to me the large spacing between elements would be a challenge. Please post results. I've got parts on the bench to build an active variactor-tuned loop but have yet to find the time. If the second element idea works, I'm in!

Mark

I have a half hearted try at a large loop. It's taking up a huge part of my lab space. I have not measured the circumference yet. I'm guessing it's 20-25 feet in cir. It's made from 3/8" copper tubing. Making it match won't be easy because it's coupled to a million things that are just laying around. Also it needs a solid feedpoint installed. Right now it's just some 24ga jumpers from a BNC connector.

I have been experimenting with 3" diameter loops just because it's so easy to make and handle.

If you know of any pics of a gamma matched type of loop where the coax connector is mounted, would help. I have a 75' length of RG8, but that's too unwieldy for my bench. So I use a 3' RG58 piece of coax and BNC connectors.

Mike

6424. SWR and gain.

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-13 18:45:00 UTC
From: Mike Phillips
Topic: 6424 Message: 6424

The last few nights, I've been experimenting with loops that I see how they respond to having a sheet of aluminum foil or copper pcb, behind them. It allows some coupling that seems to really increase gain. It's just quick and dirty tests, but it seems to be repeatable.

One thing that I found and remembered from years ago, is that a low swr does not generate a high gain. I was hitting 1.01 swr and yet the gain was low. This is where having a repeatable, mechanically solid loop antenna on my bench would help. That's why I'm looking to buy a completed loop antenna. Maybe the DeAnza swap meet will have one tomorrow.

Making one that can be tested repeatedly is another level of testing that I am aiming for.

Mike

6425. Re: SWR and gain.

Yahoo group: loopantennas (2008 — 2012)

Topic: 6424 Message: 6425

Mike,
At frequencies of 1Ghz and up, things behave differently. That is why the feedpoint is critical, a few fractions of an inch equal a significant fraction of a wavelength, where at HF, these are much less critical.
At HF, a two element beam will give around 6db gain over a dipole. In essence, it is a dipole, with a reflector element positioned around 0.2 wavelengths away. Tuning your transmitter away from the antenna's resonant frequency will increase the SWR, and reduce the effective radiated power, thus giving an apparent reduction in gain for the same power output. I really don't see how you can increase the gain AND the SWR, it just doesn't add up.
How are you measuring the gain in your example below? While low SWR doesn't GENERATE gain, high SWR doesn't either! There must be some other effect at work here.
Not to put too fine a point on it, but on this group we have almost a hundred years of accumulative research on antennas at HF.
Your best bet is to put a half wave coax fed dipole in your attic, and then compare everything else to it. The half wave dipole is the "rule of thumb" for comparing antenna performance. A trapped dipole will resonate on more frequencies, but with less gain. A random wire will work fine, especially with a tuner of some sort. The tradeoff is going to be broadband vs. gain. Typically you can have high gain at one frequency, or receive on a wide spectrum at somewhat reduced gain. Other things that affect gain will be height above ground, inside vs. outside, diameter of the conductor, and so on.
Good luck,
Pappy Hiram

Sure, I can see that.

> At HF, a two element beam will give around 6db gain over a dipole. In essence, it is a dipole, with a reflector element positioned around 0.2 wavelengths away. Tuning your transmitter away from the antenna's resonant frequency will increase the SWR, and reduce the effective radiated power, thus giving an apparent reduction in gain for the same power output. I really don't see how you can increase the gain AND the SWR, it just doesn't add up.

Maybe me using the word increase is incorrect. How about if I said improve the swr and improve the gain?

> How are you measuring the gain in your example below? While low SWR doesn't GENERATE gain, high SWR doesn't either! There must be some other effect at work here.

I'm using a Vector Network Analyser for my tests. An Advantest 3765CG. It shows the swr, gain, and Smith chart of whatever is tied to one of three ports. This unit can find the resonances of anything by sweeping from .3khz to 3.8ghz. With BMC connectors and RG8/RG58 coax there are lots of reflections and anamolies, so I stick to everything in lower range of the analyzer for HF.

> Not to put too fine a point on it, but on this group we have almost a hundred years of accumulative research on antennas at HF.

Understood. I didn't think I was debating anyone, just looking at these designs from the perspective of the analyzer. The data generated by a VNA is something to behold. When used correctly it can lend a critical perspective to any antenna design. After working with VNA's, it's ruined my perspective forever on antenna testing and design. I will try and make a video of what happens while I'm working on an antenna design and show what the analyzer is telling me. It's incredibly informative. I worked with possibly one of the best antenna designers in the world and thought I had found the best job in the world. Have you heard of Rob Hill?

> Your best bet is to put a half wave coax fed dipole in your attic, and then compare everything else to it. The half wave dipole is the "rule of thumb" for comparing antenna performance. A trapped dipole will resonate on more frequencies, but with less gain. A random wire will work fine, especially with a tuner of some sort. The trade off is going to be broadband vs. gain. Typically you can have high gain at one frequency, or receive on a wide spectrum at somewhat reduced gain. Other things that affect gain will be height above ground, inside vs. outside, diameter of the conductor, and so on.

I do need a good reference antenna. Since my old receiver only has the 'antenna' and 'ground' clips on the back, can I use coax to bring the signal down?

NVIS -- Near Vertical Incident Skywave Antenna:
The Emergency Communications Antenna

By Stephen C. Finch, AIØW

Introduction

The antenna axiom, "the higher, the better," is true for working distant stations. Generally antennas that are installed physically high up tend to have more of their radiated energy leaving the antenna at a lower angle . This causes the skip distance of our signal to be as far away as possible. Depending on the sunspot cycle, time of day, and transmitter frequency, that distance can be from 300 miles at 3.5 mhz to worldwide communications at 14-28 mhz.

But what if we need reliable communications with a station 25 or 100 miles away. Regardless of frequency, our signal skips over the close-in station and no communication is possible. Yes, there is ground wave, but in our mountainous terrain, ground wave may be only a few miles, and then not very reliable. What do we do to eliminate this "skip zone?"

Our answer is not to increase power, try to set up VHF repeaters, or other drastic measures. The answer is simple, install an NVIS antenna, select the appropriate operating frequency, and reliable communications from 0 to 300 miles becomes very achievable.

Propagation

As the signals leave the antennas, they travel up and are refracted off the various ionosphere layers. The lower the signal's incident angle and the higher the layer of refraction, the farther away from the transmitter the signal returns to earth.

For most hams' "typical operation," we seldom care where our signal lands. We are interested in communication with anyone. Sometimes, we choose frequencies to increase our chances to "work" a station in a far-distant place. Some hams pour over propagation charts, design elaborate antennas, and operate at all hours of the day and night to "bag that rare one."

When close-in, reliable communications is need, guess-work and luck is not good enough. Our understanding of frequency verses propagation becomes even more critical. What we need is propagation that covers from about 10 miles up to 400 miles with no skip zones.

We can see from the diagram to the left, that signals which leave our antenna in a near-vertical direction will travel up to the ionosphere and are reflected back. It is like spraying a hose in a fine droplet pattern, straight-up. The droplets of water fall back to earth in a pattern that covers the ground evenly with moisture close to where we are standing. The pattern from an NVIS antenna does much the same with the transmitted signal. The majority of the signal is transmitted between 75 and 90 degrees straight-up. In fact the 3D antenna pattern looks like a bowl set upside down.

The Antenna

The simplest NVIS antenna is a dipole cut for resonance on the operating frequency and installed at 1/8 wavelength above the ground. For the ARES ssb frequency of 3928 khz, the antenna would be about 120 feet long and mounted at 30 feet. With our rocky, dry ground, lowering the antenna to 20 feet may be advisable as the effective ground lies below the surface of the actual ground. In fact any height from laying the wire on the ground, to an 1/8 wavelength will work. The main difference between the higher antenna and the lower antenna is the gain or loss of the antenna.

The EZNEC pattern shows the radiation pattern for an antenna mounted 1/8 wavelength off the ground. Notice that most of the energy is between about 30 degrees both sides from vertical. This where we want the energy to go. Notice the gain of the antenna is about 6 db. This over perfect ground. It will be less over actual ground, but ant any rate, the antenna will have a positive gain.

With is this diagram, we have lowered the antenna from 1/8 wavelength (32 ft.) to 9 feet. Notice that the pattern is nearly identical. However, the antenna gain has dropped from 6 dbi to -1.37 dbi. This means that the signal radiated off the 9 ft. high antenna is less than 1/4th the signal radiated off the 32.5 ft. high antenna. While this seems significant, the questions is "Is this loss actually significant in received signal strength?"

Path Losses

Lets take a look at the received signal strength as transmitted by different transmitter output levels. The large table, Very Close-in stations, shows the received signal strength for both the 1/8 wavelength (32.5 ft.) and the 9 ft. antenna height.

Even with the low antenna of only 9 ft., the received signal strength is still an S7. Most receivers have a noise floor of better than -125 dbm. However, the average noise level of 75/80 meters is about -112 dbm or an S3. That means that for a +10 dbm SNR (signal to noise ratio),

the received signal strength must be -102 dbm or an S4-5. Notice that regardless of which antenna is used, the received signal strength is at least -82 dbm or S7 with using one watt at 9 ft. . .So even an inefficient antenna will work quite well for close-in communication.

Distance between Stations in Communication

Both antennas have a -3db bandwidth of approximately 100 degrees or 50 degrees either side of vertical. We can calculate the take-off angles required to communicate with close-in stations at various distances. Once we assume the height of the F2 -layer, simple geometry is all that is needed. The following table summarizes the antenna take-off angles needed when the F2 layer is 250 miles up.

SeparationDistance	Take-offAngle
25.0	87.14
50.0	84.29
75.0	81.47
100.0	78.69
125.0	75.96
150.0	73.30
175.0	70.71
200.0	68.20
225.0	65.77
250.0	63.43

For very close-in stations 2

Transmitting Antenna Height	Total Signal Transmitter	32.5 ft. Out Path	Signal Height 32.5 ft. At Receiver	S-Meter Reading
Output, W	db output	Gain Loss 1	Gain Input	Plus
100.0	50.0	6.2	56.2 -110.0	6.2 -47.6 S9 25
50.0	47.0	6.2	53.2 -110.0	6.2 -50.6 S9 22
25.0	44.0	6.2	50.2 -110.0	6.2 -53.6 S9 19
5.0	37.0	6.2	43.2 -110.0	6.2 -60.6 S9 12
1.0	30.0	6.2	36.2 -110.0	6.2 -67.6 S9 5

Note: -73 db is S9 at 50 ohm input.

1 As calculated by the "TwoHop" propagation program with my adjustments. Does not include transmission line losses.
2 Stations within 50 miles of each other.

Transmitting Antenna Height	Total Signal Transmitter	9 ft. Out Path	Signal Height 9 ft. At Receiver	S-Meter Reading
Output, W	db output	Gain Loss 1	Gain Input	Plus

100.0 50.0 -1.4 48.6 -110.0 -1.4 -62.8 S9 10
50.0 47.0 -1.4 45.6 -110.0 -1.4 -65.8 S9 7
25.0 44.0 -1.4 42.6 -110.0 -1.4 -68.8 S9 4
5.0 37.0 -1.4 35.6 -110.0 -1.4 -75.8 S8
1.0 30.0 -1.4 28.6 -110.0 -1.4 -82.8 S7

Selecting the Correct Frequency

Besides having low antenna height, the next most important factor is selection of the proper operating frequency. We need to select a frequency that is reflected by the F2-layer, but is not absorbed or significantly degraded by the D-layer. The higher the frequency, the less the D-layer will affect the signal. However, too high a frequency, and the signal will pass through the F2-layer.

Fortunately, we can determine the best operating frequency from propagation information on the internet and some relatively simple calculations. A good place to find the F2 critical frequency is at http://www.spacew.com/www/fof2.html. An example is shown to the left.

This map shows the F2 critical frequency, fo for the entire world. It is updated every five minutes so the map is very current. Other good URLs for links to many propagation information sites are http://solar.spacew.com/ and http://www.qsl.net/va3rj/prop_links.html.

Once we know the critical frequency, we can determine the proper operating frequency. The theory behind the selection is straight-forward. We need to select the frequency that is the highest possible without passing through the F2-layer. There are three concepts to recognize.

First, the critical frequency for the F2-layer is foF2 or just fo. This is the highest frequency that will be reflected back to earth from the F2-layer when hitting the F2-layer at a perpendicular angle, i.e. the angle of incidence is 0 degrees.. Go higher in frequency and the signal will pass thorough the F2-layer into space and is lost for communications.

Second, MUF, or maximum useable frequency, the highest frequency we can use and still achieve good reflection/refraction off the F2-layer. The formula for MUF is:

MUF = fo/sin(?)

where fo is the critical frequency and ? is the angle of incidence.

The MUF therefore is a function of the critical frequency and the angle at which the signal hits the F2-layer. Note that the frequency can be increased as the angle of incidence is lowered. In NVIS operations, we want the signal to "hit" the F2-layer at nearly a 90 degree angle. The sine of 90 degrees is 1. In fact the sine does not fall below 0.95 until the incident angle is below 72 degrees. Since nearly all the useable radiation falls within the 90 degrees + or -- 20 degrees, for an NVIS antenna, the MUF is essentially the critical frequency.

The third concept is FOT, frequency of optimum traffic. The FOT is the frequency where nearly 100% communication is achievable. The formula for FOT is:

FOT = MUF * .85
Or for an NVIS antenna
FOT = fo * .85

A amateur radio operators, we are limited to ham bands for operation. Thus, our frequency selection becomes choosing the 160, 80, 60, or 40 meter bands for our communications. As a side note, the importance of the 60 meter band becomes apparent when considering reliable emergency communications. The gap between the 80 and 40 meter bands is very large when there is a need to establish a reliable, close-in communication link.

Finally, the FOT will change from daylight to nighttime. During the day, the F1 and F2-layers separate and the D-layer forms. This favors the use of 40 meters due to much greater absorption of 80 meter signals by the D-layer. During the gray light times, 60 meters may be come the FOT.

At night, the D-layer disappears and the F1-layer merges with the F2-layer. Thus, during the day, FOT will be higher than in the nighttime. During sunspot minimums, the FOT may even be in the 160 meter range during the night. However, using 160 meter, horizontal antennas can be a problem because of size.

Using EZNEC, if the 3.715 mhz dipole is used at 1.8 mhz, the antenna losses at 30 feet height are about -3 to -4 db loss. This still means that the received signal should be greater than 10 db over the noise level when a 25 watt or greater transmitter is used. At`1.8 mhz, even though the SWR of the antenna system is very high, the additional losses due to SWR are minimal.

In Summary

In order to achieve reliable , close-in communications, normal amateur antennas may not work. To achieve reliable communications, NVIS techniques are needed. A simple resonate dipole installed at a height up to 1/8 wavelength works very well as the majority of the radiated signal goes straight up.

This "Near Vertical Incident Skywave" hits the F2-layer and is reflected back to earth equally covering the surface with signals from 10 to about 400 miles from the transmitting station. It is necessary to select the proper operating frequency in order to achieve the optimum NVIS operation. Choosing frequencies near 85% of the F2-layer critical frequency are best for use.

6432. Re: Files section?

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-14 14:24:20 UTC
From: Steve
Topic: 6428 Message: 6432

Roughly every 30 minutes, Yahoogroups generates a new page with slightly different links to the files. This is to prevent bandwidth leeching (leaching?). So if you go to a file folder, wait a bit, and try to download a file, you'll get errors. Reload the folder page, and you should be able to download.

See all this extra junk? That's what they keep altering:
<http://f1.grp.yahoofs.com/v1/YLi7ScGjzBKH4-KyVgGEETOCs9gQJ3nVRhPDxkYXkSzkRiHrtjor0_tUM3Xo4h1_hHyR_TTn-ytPoGCsavBMpQ/Daves_Loops/LoopAndRadio.jpg>

Those of you attempting to open that within the next 20 to 30 minutes (7:21am PST) will probably be able to open that link, after that it will give a "page not found" error.

But you can get tricky. Copy and paste the folder link:

http://groups.yahoo.com/group/loopantennas/files/Daves_Loops/

Now copy just the file name itself:

LoopAndRadio.jpg

Now put the two together:

<http://groups.yahoo.com/group/loopantennas/files/Daves_Loops/LoopAndRadio.jpg>

Tada! A link that works as long as the file is there.

>By Stephen C. Finch, AIØW

Hi Dave,

Again very interesting .... and nostalgic .... when I mentioned being in the Arctic I was working at a scientific research station and one of the functions we carried out was Ionospheric measurement by sounding the layers vertically and horizontally. We recorded the sounding results on film and I remember rolling the 24 hour film each morning and noting the resultant layers etc... .... We immediately coded the results and sent the results to Ottawa by CW. which in turn was forwarded on to Bolder Colorado which contributed to daily propagation reports.

The vertical hf sounding used a NVIS antenna and the horizontal sounding took place between our camp and Ottawa in the south. For this sounding we use a large rhombic antenna .... pointed south hi hi. Between sounding I often hooked up a small ham transmitter and worked stations in the Antarctic hi hi. HF propagation is interesting stuff.

Close communications ... e.g. 40-75 miles works vy well at 5 mhz with NVIS antenna ... a low dipole seems ideal. One one of my favourite portable antennas is an inverted vee about 35 mtrs long with the centre about 10 mtrs high and the wire ends near the ground. On 80 mtrs it is great at up to 150 miles and on 20m it will work well out to 600 miles.

Jim, VE3CI

6437. Need QST year/mo. that had article on a 40M mag loop made of copper tubing mounted to back of pickup truck

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-14 23:37:43 UTC
From: David Feldman
Topic: 6437 Message: 6437

Couple of years ago I remember an article in QST that described a magnetic loop built from copper tubing that was mounted to the bed stakes of a pickup truck. My QSTs are scattered and I am having trouble finding the article. Does anyone remember which issue?

Tks,

Dave

6438. Re: Files section?

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-15 04:51:04 UTC
From: Mike Phillips
Topic: 6428 Message: 6438

It cured itself tonight at least. It was odd that I had this download problem with some of my Yahoo groups at work and at home. Maybe a local issue?

Thanks for the help gents.

Mike

Was this a bad day again for the person, wo decides, what goes to SPAM and what doesn't?
My "thanks" went to spam, but more than 10 emails, which should have gone to spam, didn't!!!
This happens all the time!
Hotmail.com has a very much better, almost perfect control. but here in our yahoogroups I must from day to day be my own controller.
WHY? (If this goes to spam, I'll be very glad to to get out from this kind of a group.)

Without Best Regards,

Asunto: Re: [loopantennas] Re: [lojinhadoradioescu ta] Novos rádios na Lojinha Radioescuta !

Was this a bad day again for the person, wo decides, what goes to SPAM and what doesn't?
My "thanks" went to spam, but more than 10 emails, which should have gone to spam, didn't!!!
This happens all the time!
Hotmail.com has a very much better, almost perfect control. but here in our yahoogroups I must from day to day be my own controller.
WHY? (If this goes to spam, I'll be very glad to to get out from this kind of a group.)

Without Best Regards,
Aimo Unto Olavi Ruoho

Asunto: Re: [loopantennas] Re: [lojinhadoradioescu ta] Novos rádios na Lojinha Radioescuta !

Was this a bad day again for the person, wo decides, what goes to SPAM and what doesn't?
My "thanks" went to spam, but more than 10 emails, which should have gone to spam, didn't!!!
This happens all the time!
Hotmail.com has a very much better, almost perfect control. but here in our yahoogroups I must from day to day be my own controller.
WHY? (If this goes to spam, I'll be very glad to to get out from this kind of a group.)

Without Best Regards,
Aimo Unto Olavi Ruoho

Mike,
Oh, NOW I get it! You meant improve and I was thinking increase, which are really the opposite. Duh. Now I feel like an EEdiot.

I guess I'm jealous now. When I was a youngster climbing towers and building antennas, we didn't have antenna analyzers, other than the SWR meter and some "precision" guesswork!

I'm anxious to hear what you find after all this. Never having had the opportunity to use one myself, I'm curious if anyone else has experience with these antenna analyzers what your feelings are and how accurate are the predictions versus actual antenna performance.

Good Luck!
Pappy Hiram

Topic: 6424 Message: 6449

My bad! I'll be more specific in the future.

All I ever had in the 70's was a either a home made swr meter or a RS version.

As for analyzer accuracy, since I'm testing the actual antenna, it's hard to do poorly. Of course passing some watts through a design is the acid test. But after seeing and doing this for a time, the difference between the analyzer and the erected antenna is not a lot, since I can put the analyzer at the end of the coax to test the antenna wherever it's installed to make sure it is doing it's job.

Mike

I'm an ARRL member and did a QST article search with no luck. I searched "magnetic," and various combinations of other words that might have fit.

No joy at all.

Any chance it was in CQ?

>swr and improve the gain?

Hi,

I have to make a comment re: this gain vs SWR thing. First of all they are mutually exclusive.

The gain of an antenna can have different perspectives ... and is always in comparison to some standard.

In its basic perspective the gain of an antenna is how much it radiates in relation to some standard. It is a comment on the antenna .... not the feed line feeding the antenna, let alone whether there are any standing waves on the feed line. Further, this perspective (amount of radiation compared to a standard) makes no reference to the radiation pattern.

The second perspective ... the one most used by antenna manufacturers ... is different than the first perspective ... and describes certain advantages due to radiation distortion. If the antenna radiates more in one direction than another then the difference can be measured in terms of gain (if it is advantageous) or a loss (if it is disadvantageous)... even if the overall radiation is less in total than the standard. So a multi element antenna may actually be less efficient in that it radiates less overall ... but radiates more in one direction than another ... the difference of which being described as gain in terms of a front to back ratio. in the same sense making a vertical antenna longer may lower the radiation pattern putting more radiation out at a useful angle ... this difference in radiation pattern is again described as an increase in gain.

Non of these examples of antenna gain has anything to do with SWR..

Now there is something called ERP Effective Radiated Power ... which takes into account the first 2 perspectives of antenna gain and losses in feeding the antenna. Here SWR will take on some meaning. However, SWR itself does

not equate to power loss. Power loss is more dependent on the loss characteristics of the feed line in conjunction with SWR. Some feed lines with high SWR can have less loss than other lines with much lower SWR. In many cases SWR is a fact of life and is simply a part of the strategy.

Jim, VE3CI

Jim,
Thanks for the mail and comments.
I assume that the 'Trapper Dipoles ' were all homebrew ???? operating
as an NVIS antenna, now they would use a mobile phone no doubt hi!
Somewhere I have read of a chap called Sainsbury who wandered the Canadian
Arctic region servicing radios, but I never knew if he had an amateur call,
is it a name you have come across ????
Regards,
72, Brian, G0NSL-QRP.

Hi Brian,

The radios were commercial units ... the ones used many years ago were made by a company called Spillsbury-Tildon ... or something like that. The radios were purchased through the trappers association .... I don't remember whether they belonged to the association or the individual trappers. No mobile phones out on the lines ... unless you use a satellite phone. The antennas were made on site for sure ... simple instructions on how to make and deploy them. I fixed a lot of gear myself up there ... for the association, the Hudson's Bay company, the Joint Arctic Weather people (when you run out of plug-in units you have to fix them hi hi). as well as our own camp.

As I mentioned our camp was a research station with lots of strange equipment .... Nirvana if you are interested in electronics hi hi.

You need to stop posting while you are angry.

No one here can affect where emails show up in your email box, especially not me. You can thank the idiots out there who sign up on Yahoogroups then start marking them as spam, either because they forgot they joined, or don't know how to unsubscribe and won't ask.

Or again, maybe it is because you cross-posted the same message to a bunch of Yahoogroups.

If you think someone is asking too much for something, just don't buy from them.

QST has an even older article of a 40 meter loop using muffler tubing over a ground screen. I have a reference to it in an older Antenna Handbook. It as built about 6" over the screen so it looks to be an NVIS type antenna although it was not described as such. Copper pipe can probably be used as well although there may be a cost in transmitted bandwidth.

Unfortunately it is at home and I am at the start of a road trip so I don't have access to it.

I'm an ARRL member and did a QST article search with no luck. I searched "magnetic," and various combinations of other words that might have fit.

No joy at all.

Any chance it was in CQ?

6465. gamma match calculation

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-03-17 14:18:36 UTC
From: Paul M Tas
Topic: 6465 Message: 6465

Hello all

I am sitting here and wondering what the calculation is for the gamma match, for a transmitting mag. loop? I know that the coupling loop has a dia. of 1/5 of the loop. So what is the gamma match calculation for X and Y where X is parrallel to the loop and Y the distance from the loop?

Hi Brian,

Well you learn something every day ... I never attached the name Spilsbury to an individual. He was involved in manufacturing small portable SSB units ... and the first time I became aware of the name/company was when I saw the units. I never met him however.

Another tid-bit of radio lore .... The Hudson's Bay Co. .... originally out of the UK ... was the first commercial operation in Canada and operated many 'Northern Stores' through Northern Canada and the Arctic. Many if not most of the store managers came from the UK ... mostly Scotland. Many of my old friends are ex Hudson's Bay men. The Hudson's Bay stores pioneer radio communications in those areas. Before radio the only communications would be letters carried by ship, sled, or snow shoe hihi. The first radio gear was Amateur radio equipment using AM used by individual store men. The old Harvey Wells gear was a favourite.

It become very popular and then sometime after WWII The HBC undertook an experiment in official radio communication from their stores and contracted the manufacture of HBC transmitters (receivers were still general SW types). Whoever got the contract had the foresight to incorporate SSB instead of AM. The first batch used the 'phasing' method .... and the later batches used the Collins mechanical filters. Detailed records were kept re: their performance ... as indeed was just about everything at the stores. The HBC archives is located in Winnipeg. The old store managers kept detailed logs of all events and turned them in each year. these records are the most detailed history of Northern Canada and go back 300 years in some locations.

So you see, the reason the Native Indians and Inuit (Eskimos) adapted so easily to portable radios is that they have experienced them longer than just about anyone. Every HBC store had its radio and schedule for communications with other stores. The radio was out in the open in the store and at sched time there would always be a group huddled around listening to the communications ... about the only time kids were not allowed to make noiser. I know in my travels I often used the HBC radio to get messages out as did others in the community. Wherever you travelled it

was a key strategy to get to know the HBC man hi hi.

The old HBC radios are collectors items now.

Hi,

A friend of mine and I made a 20m DDRR antenna many years ago using old copper. I really don't recall how well it worked ... however I would caution building one today ... be sure to keep it in disguise as the value of the copper would attract undue attention hi hi

I was tuning and tweaking a small loop. About 8.5 inches in diameter. It's resonance was coming in around a few hundred mhz IIRC. Sorry I've forgotten the frequency as I'm not aiming for a particular band, just trying to remove the rust from my skills and to prove a solid concept around robust feed points.

I was using a solid 'reflector' (solid sheet of alum foil) behind it to see if it would affect anything. It sure peaked the gain but narrowband. Although the SWR was very broadband. Hmmm. I was using a piece of 28ga buss wire and an alligator clip as the gamma match. This thing was working well enough that I was going to post results. But then I went and replaced the gamma match lead with a soldered in wire. That ruined it. Adjusting it didn't help. So I soldered the alligator lead back in. Still not back to where it was by a mile. Hmmm. I think the old rule was if it's not repeatable then it's not any good. Shucks. I'll get back to it here another night. But it sure was great to stand several feet away, waving my hand in front of the loop and watching it respond. The loop was very 'hot' or in other words it was acting like a high gain antenna that was very directional. It was so hot I had to mount it to a pvc pole so it would not be influenced by surrounding metallic items. There was some coupling to the coax so I had to add a few ferrites to the coax. It helped a bit, but is still a concern.

Tuning the loop is a bit odd. The loop can resonate at 200-400mhz or at 1ghz depending on the distance to the reflector. I will be making a larger loop to get try all of these feed point and tuning experiments into a ham band. This small loop is just so easy to handle on or near the bench.

Next time I'll work on using a 1 or 2 inch ferrite for transformer type coupling. Maybe it's more repeatable.

I still can't figure out how to save screen shots off of the analyzer.

I feel like such the rookie.

Mike

Mike,
I have been casually reading your posts. I am wondering if you are testing / shooting for large or small loop antenna and what , if any, specific frequency is of your interest. I think it would help to clarify some of your observations.
 By definition anything less than 1/10 wavelenght in "diameter" is a small loop and I would venture to say that "reflector" in small loop would behave differently that full size antenna reflector. They call small loops "magnetic antennas" for good reason and I am just curious if any metallic object nearby would actually hinder the antenna performance by absorbing the prevalent magnetic field instead of reflecting it. I think pure (static) magnetic field cannot be reflected anyway.

In the end I suppose I'm looking at the broadcast bands as the end game. But I really don't have a band to shoot for as there is so much for me to research and prove/disprove. Since most of what I'll be working on uses BNC connectors, then the only other variable is the type of coupling/matching repeatability that works best. A video of what I've seen would really show how the feed point has so much influence on the function of an antenna.

Mostly the size of the loop matters for now as I have limited space to experiment with any amount of repeatability. Once the bench is cleared of the antique receiver I'm aligning, then it will be a bit easier to go after larger loop experiments.

Funny thing. I did make a loop with 3/8" diameter copper tubing that is about 6 feet long and about 4 -5 feet high just to see if I could tune it. About 20-25 feet in circumference. So far the feed point is a disaster so it's no surprise it's not tunable. I even tried an air variable cap too. Not to mention that it will couple to everything in my lab since it's so large. Once I get a solid, repeatable feed point/matching system made, then I'll apply it to this large loop to see if it can be tuned. Also I'm testing loops with the capacitive tuning gap at the top 180 degrees from the feed and also the gap at about 50 degrees up from the feed. They couple to a reflector differently. Plus I have a paper from a group showing how effective the 50 degree gap type is at 2.4 ghz.

I've got a handful of ferrites that I do not have the composition of. But they will be the first round of transformer type matching testing just to help guide me through the concept stages. I will keep an eye out for some type 73 that I read is good for transformer matching.

I also have to come up to speed on Smith charts. The analyzer shows it nicely but I have little experience interpreting it's meaning other than where the 50 ohm point is.

I just thought of a serious flaw in the large antenna. It has no gap. It's a bit flimsy and will require something at the gap that is strong for support. A dowel of some kind. Man, I've been tired lately. No surprise I that I left out the gap in that large loop.

Again vy interesting ... There is a Franklin site not far by land from Resolute Bay ... I hiked out to the site ... over a couple of days (24 hr sunlight) and found the cairn. I found a few items ... some old (vy old) cans .... apparently they were already used sealed food cans. I know that local Inuit have visited the site for years and heard of the different items that were found there ... including shoes. The Franklin expedition seems to have left there Arctic location where their ships rested and moved south with the hope of finding their way out. I know that several burial sites have been found much to the south ... almost to Hudson's Bay.

I know nothing about the Arctic exploration on the Russian side ... I am sure there are very interesting stories there as well.

Hi Group

Does any body have the value of the Peak to Null gain expected from a well contructed Frame aerial.

I would be interested in measured values from typical aerials. I would also be interested in the theoretical values that can be obtained.

I am seeing about a 20dB max peak to deep null but would like to know what I should expect theoretically.

Many thanks for looking at this Pete M0FMT.

Lots of articles on this subject right here:
http://www.google.com/search?q=40+meter+small+loop+antenna&ie=utf-8&oe=utf-8&aq=t&rls=org.mozilla:en-US:official&client=firefox-a

Before you buy materials you will want to consider how you intend to mount the beast, which should be about 6 feet on a side if square.

In my experience the hardest part is the tuning of the sense loop or "gamma match". Either is very critical. I've had better luck with the "gamma match", which is actually an autoformer. In any case you need an antenna analyzer attached directly to the loop to get it right.

Download a small loop calculator to sketch out parameters. You may ballpark component values with a small loop antenna calculator. There are also many on the Internet. Here is one:
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=19510

Hi Pete,

Are you talking about MW ?? A well designed frame loop should be able to produce a F/N front to null ratio better than 20 db. The null should be able to reduce a S9+ station to the point you can't hear it ... with abt 6db per S unit. However I don't recall seeing published figures.

Hi,

I mentioned my friend and I tried to build one for 20m ... with mixed results as I recall. I found a description in my 13th Edition of the Antenna Book which was made of 2 inch diameter automobile exhaust pipe (40m version I believe). We used standard 1/2' copper pipe as i recall about 6 ft in diameter mounted a couple of inches over the ground plane. I have never heard of the antenna since then hi hi.

Just a quick note.

I can now save screen shots of the analyzer plots. SWR, Smith chart, and gain each get their own separate screen shots in 640 x 480 bitmap resolution. This will be helpful to post with discussions.

When I get the antique receiver realigned, since the last piece of test equipment arrived yesterday, I can get back to antenna R & D.

Target has a sale on clear plastic totes. I picked the 16 quart versions and they really make lab and project organization. $3 each on sale.

I've also been reading a great deal about Arctic exploration lately. Made the mistake of reading "Actic Dreams" by Barry Lopez last January. Should have saved it for June or July. I later saved "Water and Sky" by Kesselheim for summer reading. This year "Northern Vagabond" and "Ancient Mariner" are set aside for summer reading.

"Ice Master" was one of the more interesting books about exploration disasters and survival that I've read. Shortly after I finished that, I came across a copy of John Muir's "The Cruise of the Corwin" where he had joined an expedition searching for the Jeanette.

>

There is a bit of history of Russian Arctic exploration to be found in "Wildest Alaska", and then there's "Bering", which gives considerable details about his exploration of the Alaskan coastline and the Aleutians. He was, or course, Danish but he was working for Catherine the Great at the time.

Hi Brian,

Yes, I knew VE8RCS .... located up in Alert on Ellesmere Island ... Canadian Forces Base. I was up in Resolute Bay on Cornwallis Island during the early 60's. I ran a ham station VE8LG while there. The Canadian Air force supplied us and Alert using the old C-119 (flying boxcar) aircraft ... before the C-130 came on the scene. The peace time flying range of the C-119 wouldn't allow direct flight from Resolute to Alert ... requiring a stop over in Tulle Greenland (US air base) for refueling. Travel on the Air Force plane was quite informal at that time ... which would allow hitching a ride to Thule .... and an overnight at the Sergeant's mess and a trip to the duty free shop hi hi... then pickup the flight home. Never managed to go all the way to Alert hi hi.

Interesting your comment on the Scott expedition to the Antarctic ... es how supplies and other items seem to last for a very long time. When in the Arctic I remember regularly contacting the Antarctic on 20m. We had a large Rhombic antenna pointing South (where else hi). I believe the call is still registered ... but not sure how active it is. The number of gov't presence in the Arctic has been going down ... but I understand there is a new resurgence.

I have some old pictures of VE8LG ham station (in a shack on skiis). If I can dig them out I'll post them.

Jim, VE3CI

6491. 8.5 inch proto loop pics and plots.

Yahoo group: loopantennas (2008 — 2012)

From: Mike Phillips
Topic: 6491 Message: 6491

Since I was going to start testing a couple of other loops, I thought that getting this 8.5 inch one documented was a good idea tonight. I think that even though the 946mhz resonance is not useful for anything I have a receiver for, it proves the concept of coupling a director to a loop can give it super directionality, and some decent gain although a bit narrow band. Testing parasitic loops installed inside of the main loop is also on the drawing board for enhanced broad band effect, since I've seen great data for it already. This loop's bandwidth is about 10mhz on about a 1ghz antenna. We use to call that a 1% antenna, which is nothing special. As opposed to 3% which has far better bandwidth. We'll see if this range of percentages applies to sw and mw band antennas when I eventually get there for testing.

Hi Jim

Many thanks for the info. You are confirming my belief based upon my trials on 500kc/s.
I have been talking to Lloyd Butler VK5BR an Old Timer who I know from is articles has a lot of knowledge in this area. He said it was a good question!!!
He listed some of the practicle limiting effects that could reduce the difference such as a/ it being a "Box" type antenna b/ the feed leads can pick up the verical element of the wave. c/ the input to the amp not necessarily being fully balanced ...etc. all very good points. He made a statement that 30dBs may be obtainable with a well designed Frame antenna. From the an early Admiralty Handbook it suggested that a "Pancake" design would perform better than the "Box" design. That kind of makes sense ..... so thats what I will do; try and compare the two types of antenna and improve the "Box" design to reduce the undesirable effects listed above.

Well Jim you are the only person on the group that put his head over the parapit and for that I thank you very much it's been a great help.

There may be a PhD in this if Lloyd is right ... but sadly too late in the day to be relevant.... HI.

Thanks Jim GL and 73 Pete M0FMT.

Chris,
Thank you for your comments on this thread, I have noted the books to follow-up.
Thanks to the list moderator, I seem to have ' wandered ' a little from the radio path hi!

Even though it's far off-topic, I enjoyed hearing from others who have an avid interest on Arctic exploration. I have many other books yet to read, and would like to find a copy of one written by Vilhjalmur Stefansson, who was probably the single most incompetent Arctic explorer of record. His disregard for others resulted in the loss of life of the members of the Karluk in 1913-1914.

Another interesting book is "My Polar Flights" by Umberto Nobile, in which he describes the crash and subsequent rescue of the survivors of the airship (dirigible) Italia, which was slammed against the ice cap by a severe storm. The incident was made into a movie named "The Red Tent", which has a very vivid depiction of the crash.

Hi Again,

VK5BR is correct. The null of the loop is dependent on loop symmetry. This in my view is the main reason for using a 'shield' construction. The shield itself provides the rigid symmetrical construction essential for symmetry ... while the loop winding itself only couples the RF to the radio. The shortcoming of this approach is that the loop itself (the so-called shield) is not tuned. The overall signal may not be as strong ... but the symmetry provides a very defined deep dull.

Extraneous signals ... such as common mode currents on the feed line must be avoided. In direction finding an extraneous signal is added in a controlled manner from a separate 'sense' antenna .... which can determine which null (there are 2 of them 180 deg apart) faces the signal source.

Jim

Did you ever work Harv Clark....VE7TO (I think?)...he was of course
working with a VE8mobile....stationed with the RCAF at Cape Perry or
somewhere like that. The time frame would fit perfectly.
Now forgive my memory but he "may not" have had the VE7TO call at
that time....he may have received it after he got back to Vancouver
and retired. Harv at one time was the oldest RCAF fighter pilot.
He had been an exchange pilot to the USAF in the late '50s. He was
flying the F-101 VooDoo down there and trained RCAF pilots on them
when we transitioned to the CF-101 VooDoo here.

I would have been in my early teens....I sat at his Collins receiver
and listen to him work many...his wife would come into the shack and listen.

Ken

Hi Ken,

I don't recall working Harv Clark .... but your right it would have been around the same time. It was a long time ago ... he must have been settled in to have a collins receiver at that time. I used either homebrew or military surplus hi hi. My personal shack was out in a trailer on skiis ... However we did have some nice gear in the regular radio room .... and we had a great antenna .... a Rhombic ... which is a kind of terminated loop. I used to use it on the ham bands every now and then running a qrp tube rig ... which was not very usual in those days. 3 or 4 watts output was all I needed with that big Rhombic antenna !!

6511. Wire material

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-04-14 05:36:05 UTC
From: Mike, KD7MG
Topic: 6511 Message: 6511

Greetings,

I'm new to the group and have searched the previous posts, but haven't seen this topic. If it's been covered, I apologize.

I'm about to put up a full-wave 80 Meter horizontal square loop at about 40' elev. and would like some suggestions on the type of wire material that would work best. This will be for a city's ECC, so I would really like it to last for about 10-20 years without fussing with it. It also will have to meet NEC codes, so if I understand them correctly, this will have to be 12awg (or larger) because of the span length on each side.

Here's the options as I see them. (Please add more options if I missed some.)

Option 1) Copper wire or copper-clad steel

Option 2) Solid or stranded

Option 2a) If stranded, roughly how many strands? (Regular, or that really fine stuff?)

Option 3) Bare wire or insulated

Option 3a) If insulated, what material?

I appreciate your help on this.

Mike

Thanks for remembering my humble person, Mark!
Yes, I like very much my small Chinese Loop BCL-01A
V2.0 (2nd edition) shortwave antenna small ring. Frequency
5 MHz - 19 MHz.
Unfortunately I never had monetary opportunity to buy
the famous AOR Loop... I think, that the AOR models
are more capable but also a lot more expencive, too...
That was the main reason for the Chinese radio amateurs
to try to "copy" the AOR loop, as they say. They did it
quite well in deed!
You may be well aware of the fact, that a ferrite antenna
may be connected with this amplifier to be able to receive
AM frequencies betw. 520 - 1620 kHz? I made some
ferrite rod antennas to test this, with varying results...
My problem is to divide myself in this hobby into too
many pieces. There are so many interesting things to be
made and tested!
I think, that it is a pity, that the Chinese group stopped
producing these loops. They really showed great talent
in constructing these marvellously good and CHEAP
antennae. We may never underestimate these Asian
brothers, as many people do. The latter ones do not give
honour to their own brains...

Thanks again for paying interest.

Hi Mike

First, NEC codes do not apply to building an antenna. The best material is copper at #14 gauge minimum. For strength you could use copper clad steel wire (only the surface needs to be copper since RF is limited to the surface). Ordinary #14 copper has no problem giving reasonable life over the kind of spans you mention (65 to 130 ft) I have had those spans up for years with #14 copper (standard electrical insulated wire). I have used bare copper and insulated electrical copper and actually feel the insulated wire seems to last longer. To insure long life ... pay special attention to contact points. If the wire terminates in an insulator it will last many years ... if the wire rubs back and forth ... eg running through an insulator or over a tree branch ... it will have limited life. If you switch to stranded #14 copper it seems to be more durable than solid copper.

For me insulation is incidental ... eg the kind of wire I can get. As far a performance I have detected zero difference in electrical performance. As far as ease of handling ... solid copper is good, stranded copper more difficult, insulated better than non insulated. Very fine (flex wire) is very easy to use (like rope). Copper clad steel the most difficult.

I hope this helps.

6515. High-pass (BCB) filter as part of a receiving loop - seeking ideas/recommendations

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-04-17 23:50:57 UTC
From: David Feldman
Topic: 6515 Message: 6515

General question - I'm looking for ideas on incorporating a high-pass filter (with cut-off at 1.7 MHz or so) into a receive loop so that the loop's preamplifier (at the feedpoint) isn't overwhelmed by BC signals. How would I go about estimating the feedpoint impedance at the loop's feed point so I can incorporate that into filter design? Ideally I'd like a loop that incorporates a wideband preamplifier at the feedpoint but where the preamplifier is protected from BC signals (of which several are quite strong here due to broadcast stations a few miles away).

Thanks,

73 Dave WB0GAZ wb0gaz@...

Thanks for your input, Jim. Regarding the NEC, I was first alerted to it years ago while reading the (many) comments following the following eHam article.

http://www.eham.net/articles/10959

About halfway down, K8MHZ made a reference to the NEC, that I took as fact, until I just looked it up for myself. He said, "Spans over 45 feet must
use either #10 hard drawn copper or #12 copper clad steel, bronze or other high-strength material." This was based on the table shown in 810.52 of the code. When I just now looked it up, it actually said "When maximum open span length is over 45 m", NOT 45 feet, so according to the table, using #14 wire of any type will satisfy code requirements for an 80m loop. (Should have listened to you from the beginning. lol)

Since I've posted this article, I've consulted with several old-timers who agree with you on many points. Here's what I learned.

1. Stranded will typically last longer than solid in most environments like mine (N. Utah) where occasional high wind is a factor.

2. If you go with stranded, they recommend it be insulated with something that's UV resistant. The standard THHN found in hardware stores is OK, but the nylon "skin" cracks and peels after a while. It doesn't change the performance, but it looks kind of ugly. Insulation also keeps ice from forming between the strands which can make loud "crashes" when the wind breaks it up.

3. Copper or copper-clad steel is a matter of preference and availability.

4. Like you mentioned, performance is virtually identical no matter what kind of wire you throw up there. The question is, how long do you need it to stay up?

One recommended the POLYS-13 wire from Davis RF for a good strong stranded copper clad steel wire with a durable UV resistant jacket. This sounds right in the ballpark of what I need. Any other suggestions that's maybe a little less expensive than $0.24/ft?

Thanks,
Mike

Equally important as the wire is what you are going to use to hold it up there.
I presume you are going to use halyards in each corner so you will need a good quality UV resistant rope - black seems to be the best.
Hams in your area will no doubt have some information on what lasts the longest.

I'm going to be living full time in a travel traler running around the country. I was thinking of putting up a loop on top of the trailer. I want to like the FCC use to do running around towns. I want it to be able to rotate it around to p/u on signals. Now what would be a good way to install it. And how would I prevent the lead in cable from getting all twisted up? Thanks
Ted

In a situation like this, where the labor costs of putting up the wire will greatly exceed the material cost, it doesn't make much sense to use anything but the strongest. I'd go with 12 AWG solid copper clad steel. You'll have no issues with codes so won't have to worry about whether they apply or not. And with a breaking strength of 900lbs or more, it would take a large felled tree or one heck of a big wind to bring down the wire. The Wire Man<http://thewireman.com/antennap.html>sells this stuff for $0.15/foot in the length you'll need.

So true! They all recommended black Dacron rope with 3/16 being the most common used. I'm planning on using an egg insulator in each corner. One side of the loop will be between 2 towers, with the opposite side between large tree trunks. The towers should be OK, but I know the trees will sway somewhat, even through the trunks are still about 2' across at 40' up. (Big trees!) It will be corner-fed with window line at one of the towers.

I was planning on tensioning it at the feed corner with a weight or spring (hadn't gotten that far yet), with the opposite corner strapped so the wire couldn't slide through the insulator. The 2 other corners would be left to slide free. Something like that anyway.

I've constructed and installed several 160M delta loops and use commercial .130 nylon trimmer line - the stuff the landscapers use in their gas powered trimmers. Fabricate a few wood cleats to lag screw into your trees to secure the trimmer line - and be sure to get the ROUND line, not the type with the square edge. It will saw awyay at the branches...the ROUND type kinda rolls.

I've had mine up for a few years. The stuff will stretch but won't break easily. It fades in UV but still remains flexible. Even when an antenna loads up with ice, the trimmer line still holds - of course it will stretch, but when the ice melts, back up goes the antenna. And no damage to the tree branches.

Use leather gloves to pull the trimmer line and 3/4 inch pvc pipe as insulators. I drill a few holes and weave the wire in and out. If you need a "floating" loop, then egg insulators are the way to go - I've got an 80M horizontal loop that is a "floater."

And on a side note: the pneumatic tennis ball launcher is the best method I have fund for putting lines up over the tall trees or covering a wide expanse between trees. With a

weighted tennis ball and 70 or 80 psi of air (I add a few ounces of sand to the inside of mine and reseal them with hot melt glue) I can launch a line over a 100 foot tree with room to spare. With 100 psi and a good 45 degree angle shot I can cover a few hundred feet.

Interesting. I've read about a lot of materials but not trimmer line. lol Might have a bit too much stretch in it, but certainly something else to look into.

Yes, this will also be an 80M floater and I was already planning on using egg-insulators at the corners. Thanks for the tip though.

> And on a side note: the pneumatic tennis ball launcher is the best method I have fund for putting lines up over the tall trees or covering a wide expanse between trees. I borrowed my son's potato gun once to launch a line with a weighted ball and laughed as I read a recent article about that in QST. Fortunately, I've got something slightly safer at my disposal. A Hi-Ranger bucket truck with a 65' reach! 8^)

(trimmed)

I've found the 500' rolls of 14 ga and 12 ga stranded insulated wire at Home Depot. Available in a variety of colors, I purchased black. The 14 gauge wire is $25/roll. The 12 gauge wire is $40/roll.

For rope, I use black parachute cord. This can be found via Google search. You can buy other colors, but black seems to disappear into the background. I bought a 250' spool.

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

6526. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-05-01 13:27:57 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6526

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

6529. G4HOL Loop details

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-05-02 20:59:56 UTC
From: M HOLDEN
Topic: 6529 Message: 6529

My golden rules: Avoid the use of coax cable as an H.F. loop feeder. (It will unbalance the system and could therefore produce unwanted received noise [QRN])

The formula 1005/f(MHz) is good from hf through to uhf. This will be the total length of a full wave loop in Feet.

Use medium impedance twin like 300Wslotted if you are going to make one loop work on multiple frequencies, as most of the time the "seen" impedance at the loop feedpoint will also be "medium". The system will remain in balance and therefore reject QRN.

When using a single band full wave loop antenna, the best match to a 50Wtransceiver will be a quarter wave or an odd number of multiple quarter waves of 75 / 80Wpolythene twin. Do not ignore the manufacturer's Velocity Factor of the cable. A VF of say 90% will mean that the feeder length will be 90% of a quarter wave long. Read up and understand the use of quarter wave line impedance transformation. The 234 divided by f (MHz) will give a true quarter wave of copper wire, in Feet. If you make a good 40 metre loop it should work well on 15 metres too.

A current balun at the antenna tuner end of the feeder may not be needed as it could be transforming already low impedances even lower and beyond the range of some tuners capabilities.

I enclose my optimised HF loop design as well as a 2lvhf design which will work well on the lowest budget and with dual polarity.

The Cebik website will go into greater depths, but there is enough here to wet the appetite.

Mike G4HOL

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

From: Steve
Topic: 5136 Message: 6531

I could use some help with the links. I moderate about twenty groups and I'm a full time student right now. Some have offered to help, but none have come through.

A quick Google shows JLKolb has put his stuff on another site. I started going through the links and correcting them, but I just haven't had time.

Ideally, these would all go into the Links section, but Yahoogroups gives no simple way to get them all in except one at a time.

6532. Performance of broadband loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-05-03 03:07:46 UTC
From: greg_ella53
Topic: 6532 Message: 6532

The files section shows two posts from May 2007 for a broadband untuned loop that is square, six feet or more per side, vertically mounted and transformer coupled. I would appreciate hearing from anyone that has built one of these, regarding performance and coverage over the HF band.

Thanks much,

Greg Ella,
Livermore, CA

Thanks for that Lee. When you have a simple monoband antenna your solution is sound. When you change frequencies on a multiband loop, you also see large changes in feedpoint impedances. These are in the range of "medium" impedance, and 300 ohm or 450 ohm ladder feeder is far better equipped for that than coax at 50 or 75 ohms. I experimented some years ago with a 150Ft loop using a ferrite ring coupling. I was not too impressed with the heat generated in the ferrite. I know of others who have used the loop on auto tuners at the feedpoint, (and have dispensed with the ladder line) and had great results on 50 ohm cable running back to the rig in the shack. I am sorry that my omega signs and lambdas became W and l in the print up earlier, as this must have caused some confusion. Best wishes, Mike G4HOL

One problem folks learned many moons ago with balanced feeders was that whether sized/spaced for 300, 450, 0r 600 Ohms characteristic impedance was unimportant if the load (aerial) did not match that impedance. Sure, a well thought out balanced tuner could 'match' a pair of bed springs fed with ladder line - or so a VSWR bridge in the coax feed would indicate. The feedline would be part of the load, in the mismatched aerial case, and radiation would commence 'in the shack'. On receive, some signal pickup would occur on the feedline, too. The benefit of the matching ferrite toroidal transformer at the loop's feedpoint is that the coax feed, even with a non-negligible VSWR, is still well-shielded. Also, the Hi-Z winding can be split - with a grounded CT to keep from developing static charges on the loop.

Before 1972, the Marine Band in the USA ran from 2-3 MHz AM. Since then, it has been VHF NBFM - around the NOAA/Marine WX frequencies. Small craft that needed communications in the latter years used a transceiver, often with a single 12V filament sweep tube PA plate modulated by a solid state audio amp, running 30-50W RF. The 'channels' were significantly apart, frequency-wise, and the output Pi-network was adjusted, ie, tapped, for each channel - and the length of 'feedline' (insulated wire) and height of the mast could not be altered for fear of detuning the transmitter. Touching it while it was in use could result in an RF burn, too. Designed 'RF in the shack' - but I digress..John

6538. dumb question for ya all

Hey gang.....long time since I have been on here. I ahd a few questions for the group and was hoping that IU could get some input.

I would like to build a vertical loop, mainly for 30 meters. I am leaning towards a vertical oriented loop. I have a 90 foot tower and was going to hang the loop from that. I have enough room to hang a 30 meter loop, however my question is this.....can you use the loop that is cut for 30 on 14, 18, 21, and 28? Or should I cut the loop for 40 meters?

Also, if I go with the verticaly hung loop, fed at the bottom corner with open wire, that should give me a lower angle of radiation, which would be better for DX, right? One more question,,, in your experiences, which loop was better as far as noise was concerned? A horizontal or a vertical loop.

Thanks again to all for your time. I am re-learning the theory aspect of the hobby, primarily antennas. Any input would be greatly appreciated.

Thanks and 73's to you

Hi,

Generally speaking in harmonically related situations a 1 wavelength loop radiates perpendicular to its plane on the fundamental frequency and off the side of the loop on its harmonics. If you used a 40m vertical loop the radiation pattern would be predictable on 40m and 20-10m. Not sure what it would be on 30m. I suspect it would be more like 40m than 20-10m. Personally I would go for a loop 1 wavelength on 40m .... performance on 30m would probably be similar to 40m while higher harmonics would be off the side.

You definitely have to go for a vertical orientation. If you go for a horizontal orientation and you want reasonable performance on 30m you would need a loop at 1 wavelength at 80 m at least.... anything smaller would give excessive radiation upwards on 40 and 30 rather than reasonable horizontal angles for dx.

Jim, VE3CI

For what it's worth, I run a 5MHz loop (which is a low slung horizontal) and it works very well from 3.5MHz through to 28MHz. It is fed with 300ohm slotted ribbon, right back to the shack. If I had a 90Ft tower, (I WISH!) I would hang it high as a vertical triangular loop and run the feeder into a bottom corner. Mine is 188ft 6ins circumference. It would be approximately 2 wavelengths on 10 MHz and have low noise receive characteristics. I am unaware that a change of polarization would change the noise performance.
Best wishes, Mike G4HOL
P.S.The dumbest question is the one that is never asked. Seek and ye shall find!

Subject: [loopantennas] dumb question for ya all

Hey gang.....long time since I have been on here. I ahd a few questions for the group and was hoping that IU could get some input.

I would like to build a vertical loop, mainly for 30 meters. I am leaning towards a vertical oriented loop. I have a 90 foot tower and was going to hang the loop from that. I have enough room to hang a 30 meter loop, however my question is this.....can you use the loop that is cut for 30 on 14, 18, 21, and 28? Or should I cut the loop for 40 meters?

Also, if I go with the verticaly hung loop, fed at the bottom corner with open wire, that should give me a lower angle of radiation, which would be better for DX, right? One more question,,, in your experiences, which loop was better as far as noise was concerned? A horizontal or a vertical loop.

Thanks again to all for your time. I am re-learning the theory aspect of the hobby, primarily antennas. Any input would be greatly appreciated.

Thanks and 73's to you

For what it's worth, I run a 5MHz loop (which is a low slung horizontal) and it works very well from 3.5MHz through to 28MHz. It is fed with 300ohm slotted ribbon, right back to the shack. If I had a 90Ft tower, (I WISH!) I would hang it high as a vertical triangular loop and run the feeder into a bottom corner. Mine is 188ft 6ins circumference. It would be approximately 2 wavelengths on 10 MHz and have low noise receive characteristics. I am unaware that a change of polarization would change the noise performance.
Best wishes, Mike G4HOL
P.S.The dumbest question is the one that is never asked. Seek and ye shall find!

Thanks to all for the replies that you sent. I might be able to string a 80 meter loop from the tower, however, I think that it would not end up in a perfect diamond shape, not to mention that the lowest point would be pretty close to the ground. I guess I am looking for options here as far as the best antenna that I could hang and get the best results, ie. dx and noise factor.

To give you a little bit of a description of the tower situation that I have, it is a 90 foot, Rohn 25 guyed 3 x 4. By that I mean that it has 4 anchor points, with 3 levels of guys. These guys are not insulated, which leads me to beleive that the tower / guys will have an impact on the performance of the loop. Currently I have a dipole, basically, cut for 160, with the eastern end up at 15 feet and the western end up about 25 or 30 feet or so, fed with homebrew 600 ohm ladder line. It does a fine job on 20 as well as 30, however the antenna is running basically east and west, with the broadside being north and south. So wanting to work Europe and such, I think it is 'pointed' in the wrong direction.

I was wondering if I should stick with a vertically hung loop, or a horizontally hung loop. If I were to go with the horizontally hung loop, maybe I could get 30 feet up on all four corners. For topband, I know that this will be burning not only worms, but clouds as well. I was also wondering about feedline length. 1/4 wave comes to mind for the lowest band of operation. If my memory serve me right, I think that I have about 230 feet of open wire feedline feeding the dipole. Should I trim it back a few feet? Or, leave it as is.

Again, thanks for all your input. I am still trying to learn the whole aspect of antenna theory. Bear with me!! HI HI Hope you all had a good weekend and thanks again for your advice on this subject.

Hi Scott. To ease your worries, loops are not worried by nearby objects anything like as much as yagis and resonant dipoles etc. Slope, symmetry and shape also pale into virtual insignificance. So you could have a "horizontal" loop with one corner at 90 Ft and others at 30 Ft, if that was available. If you are making a dipole, you have to be accurate. With a loop, you can take a more laid back approach - like suck it and see ! The feed length is not an issue as it is non-radiating and in near-perfect balance at all times on all bands. My rule of thumb is to use a convenient length of feeder, (historically anything from 15 to 60 Ft at various QTHs. There are two schools of thought about actual loop size. One is to use 1005/f and cut for specific resonance, and multiples thereof. The other is to use as much wire as possible, hang it high and bring it to resonance on tuned feeders with the atu or auto atu in the shack. Both work ! Just go for it. You
will not be disappointed. Kind regards de Mike, G4HOL

Hello I just ordered the RPA-1 preamp and was wondering if any of you are using one and what configuration antenna?

I was thinking of using it in a loop setup maybe something like the Wellbrook ALA 100 unit they use maybe a forty foot loop of plain copper wire or they have use a 3 turn 6 foot diameter of wire

basicly a balanced loop

Am interested in the MW band would like a bit of front to side

thanks appreciate any information

Leon

Hi Leon,

I use one with my homebrew K9AY loop for 160m operation as well as BCB listening.
Very effective. I have mine mounted on the wall of the shack right behind my K3.

Antenna is down now for the summer. Mainly a winter time activity for me.

Hi all,
I have same problem with external input impedance of my Degen1103.
In these days I building an external antenna for LF-MW (150k - 1.7M).
In that "ferrite antenna" I want to connect a secondary loop to take signal,but
I don't know the impedance of degen and I don't know how to calculate the turns
ratio between main loop (loop to connect with variable capacitors)and feeding
loop (to connect with external input in Degen)
Below the schematics of my external ferrite antenna.
http://img193.imageshack.us/my.php?image=ferriteantenna.jpg
Sorry for bad drawing....the writen are in italin,but in the left side of
drawing says variable capacitors and in the right side says to degen input.

Who can help me?

regards

Ciccio

ok! 600ohm in the center of frequeny tuned.but....
I think,
at the resonance ZC and ZL are same.
I choose Q value for the selective. (high Q = High selective)
Zfeed = Q*ZL ?! right?!
Zd is input impedance of Degen (600ohm)
N is turn number of feeding loop

N = radquad((ZC * Q) / Zd)

Right?or not?

Regards

Ale

You're confusing tuned resonance with impedances for the application.

Your coil will have an inductive reactance of XL = 2*pi*fL; L is the inductance and f is freq.

ZL = R+XL; R is the wire resistance in ohm. This is the Z for your main winding.

If you don't know the R value, don't worry, it's smll compared to a ferrite winding's XL.

To match your 600 ohm, use the fact that the SQUARE of the turns ratio is the impedance ratio; thus, a 3:1 turn ratio yields a 10:1 impedance ratio [approximately].

Let's say you want to have the unit to tune from 520kHz to 1710kHz, and the median freq is thus 1115kHz. Use 1100, it's close enough. fc=1.1 MHz, which s your design freq for the coil.

The ferrite will have its own characteristics in uH/turn^2 or something similar. Once you know this, assuming the coil is on the centre, then you can determine the number of turns needed to achieve resonance for 1100 kHz, with the tuning capacitor you plan to use.

Knowing this turns ratio and inductance value [best measured, but estimates can be close sometimes!] you can then find XL using 1100kHz as your f value - take XL/600 nd then the sqaure root. This number is your turns ratio. Apply the nearest whole number and you're done.

that is what I thought but then got to thinking about the interaction effect of the tuned resonant adjacent winding and therefore did not answer

however we agree to try this first the design of the second loop for inductive value near 400 to 800 ohms at the centre frequency of interest

best to use a inductance meter if you have one around

if you do not have one and have 100$+ or so I highly recommend the AADE LC meter purchased assembled and tested, hard to beat this beauty

best wishes

WARNING the DE1103 DOES NOT ALLOW EXTERNAL ANTENNA JACK CONNECTION FOR AM BCB/MW. (UNLESS YOU USE THE "TRICK"). THIS IS A HACK AND NOT IN THE MANUAL. THE MW ANTENNA IS A TYPICAL LOOP STICK AND NORMALLY TO ONLY WAY TO COUPLE IS PASSIVELY (WITH OUT THE TRICK).

The antenna input is 400 ohms, pretty well set up for a a 30-foot random wire. The DE1103 has a interesting antenna match system (SEE SOME REF LINKS BELOW). Join the DE1103 Group for more info.

I have a DE1103 (same as KA1103). Highly recommend. The best deal on the market.

The external Antenna Jack is only for SW/FM and does not work for MW, only works for SW. However there is a TRICK to allow the external antenna jack to work on MW and LW. See "TRICK" below:

Here is a review:
http://www.radiointel.com/review-degende1103.htm

Here is the technical info
http://www.ukradio.info/Degen/

Another Review and comparison (CUT THE WHOLE LONG LINK):

http://f1.grp.yahoofs.com/v1/ABIcSlNLc6UL1HlbWJ54kKrnWlRPDmMG-b58JyJYEDMGHyb-uOelj1e1NBfWQ7y_b9BPDxYo6yF6By2W-35AyZSp8-s_LEMqcu0/mtrevumay07.pdf

Manual:

http://f1.grp.yahoofs.com/v1/ABIcSj66stoL1HlbEOZRvpiUj2EL-wZ6yxTaGTTWcXIcKZ3jdSE--MYwks5nA-0R8Xtz2DDBdPOMZVIKDtBBsWmH66aWCY_0TQo/DE1103.pdf

TRICK!

It is possible to tune the 1103 receivers below 100kHz, and to
disconnect the internal ferrite rod antenna on MW + LW, by using
this simple procedure with the SCAN function.

Normally, a 'scan' will remain within the selected band, with
the tuning scale showing progress through the band. If you start
a scan from outside a band, the scan will become 'trapped' within
the next band that is reached. However, starting between 1 & 9kHz
above any band upper edge and scanning down, will bypass the 'band'
system, and will not switch to the ferrite rod in the range 1710 -
100kHz. The tuning will also continue below 100kHz.

So, select 1711 by direct entry:
[1] [7] [1] [1] [band+/AM]
and scan down: hold [BAND-] for 2 seconds.
As soon as the frequency is below 1710kHz you can stop the scan and

use the rotary control, or you can let the scan continue below 100kHz.
The antenna is now switched for the telescopic or external antenna.
I suggest you tune it down to zero and store this in preset 0, or store
99kHz in preset 99. Also store any frequencies for which you wish to
use the external antenna input. You can store any frequency with the
[SSB] mode 'on' for CW reception.
Once you tune above 1710 again, the system will revert to the normal
tuning range with the ferrite rod for MW + LW.

There is another procedure at http://mods.radioscanner.ru/degen/mod29/
for tuning above 30MHz (AM), possibly up to 35 - 37MHz depending on
hardware alignment

IT IS about 400 ohms but see my other post (just posted) on how to connect the extenral jack and disconnect the internal MW loop stick. There is a hack or trick.

It is a great radio, join the DE1103 group. There are great links, files and info on the group.

Have checked the Wellbrook website???

http://www.wellbrook.uk.com/

I don't see much difference other than the 100 can use a bigger loop.

6562. [loopantennas] ALA 100 VS ALA 100M

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-05-30 07:48:23 UTC
From: Dominique KREMP
Topic: 6559 Message: 6562

Hi James,

I've been using both of them for a couple of years.
I agree with Don, I must say I NEVER saw any difference between them, it's like their price.
Same sensivity and same noise (if any !).
Surely a spectrum analyzer might show various 3rd order intercept points, my ears don't !
Just the loop has to be larger for the 100 version than for the 100M.
To sum up: it's the same different, but they are very fine antennas !

Hope it helps !
Have a nice w.e.

Dominique

6563. McKay Dymek DA100E

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-05-30 22:37:44 UTC
From: Greg Bowne
Topic: 6559 Message: 6563

I have a McKay Dymek DA100E active antenna that needs the AC adapter power plug wall wart that goes to the control box. If anyone has a DA100E could tell me more information about the adapter that comes with it, I would most appreciate it. If not, perhaps someone could tell me where to get the right one. I especially need to know the power requirements for the antenna control box.. The information nearest the power jack was not specific enough.

Thanks,
Greg Bowne
Seattle, WA USA

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

6565. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-06-01 13:09:07 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6565

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Date: 2009-06-01 15:01:37 UTC
From: C. Beijersbergen
Topic: 5773 Message: 6568

On a more or less regular basis we get this mail sent to us. Very often one or more of the members react by saying that a large number of the links are not working any longer. But after that nothing happens.
Now again we receive this list. Because the first one on top of the list looked familiar to me (I sent a correction about a year ago) I cjecked it and indeed it is still not working. This brought me to checking all links. Result: from the about 110 links (a number are doubles) 49 were not working any longer now and most of them have not been working for quite some time.
I think it is a waste of time and energy to send this list every time again unchanged.

I will place my version of the list in the files section with the working files in green and the not working files in red (this is working for me, today June 1st, 2009).

I've requested help with this before and several have volunteered, but you are the first to take action. Thank you.

I'm reluctant to just delete the bad links. I find often they are just moved elsewhere.

I've gone through the first four pages, aided by having the bad links marked in red, and found where several have moved, and confirmed that several companies have shut down. JLKolb just has his stuff on a new site, thankfully. A couple of manufacturers have new models so the links to the old models are unworking, but there are replacements.

There are 9 pages left. I'm uploading what I have so far. I'm back in school so my time is very limited, so I'll work on this more as I have a few free minutes.

Thank you,
Steve Greenfield

73 de Yakov, VE7ALQ
=============

Yes I own one. Bought it almost 2 years ago when I moved from a
house to an apartment. It sits on my balcony on the 30th floor in
the middle of downtown Toronto.

It's a VERY high-Q antenna, especially on the higher bands of 20 and
15 metres. As such it is very easy to spoil the Q if the antenna is
too close to metal or other dense materials. The rebar in the
concrete on my balcony can affect the Q and spoil the SWR if I don't
make sure the antenna is in the middle of the balcony. I can't put
the antenna within 3 or 4 feet of any concrete wall.

This is a fantastic transmitting antenna. I use mine in the
horizontal position so the nulls are pointing up and down therefore
it is acting like an omni directional antenna. If you prefer to use
this antenna in the vertical position, the nulls are pointing out
the sides and the antenna can then be used as a directional antenna.
This might be useful if you have some directional local QRM you
want to null out.

The con with this antenna is that it is not a good antenna for
someone who likes to frequency hop or band scan. When receiving,
this antenna needs to be retuned every 50 - 100 kHz (depending which
band you are on) or the incoming signal strength drops off
drastically. That's why I call it a very high-Q antenna. But if
you like to operate in just a CW portion or SSB portion of a band
you can tune it for the middle and then listen up and down from
there about 50kHz - 75kHz each side, so it's not bad for people who
don't scan all over the HF bands constantly.

It really is excellent for receiving in a noisy (QRM) environment
such as a big city as the magnetic loop doesn't pick up the E-field
as well as it picks up the H-field. Most local man-made noise is
vertically polarize E-field.

I think it is a bit expensive for what you're getting. Aluminum tube, servo motor, capacitor and control box. Mine is holding out well so far and I work DX quite well with it.

Hope that helps.

73,

Tom Curtola

Happy ATSC day, Analog (NTSC) TV is dead

How did it affect you? Me? I am on digital cable so no big deal.

However I have a few analog TV's. I put the rabbit ears on and took a look today. YEP there are some channels, PBS, Spanish still on. The main network over air stations are off, except one is playing a repeating PSA about the switch to digital TV.

I tried Digital TV (over the air) 6 months ago for grins, and I have to say I am impressed. It is not the content of digital cable, but better picture, audio and more channels than analog could ever hope to be. I think I got 19 over air channels. Most stations have been on digital simultaneously with analog. I have one portable B&W (AC/DC) AM/FM TV I won in a raffle 25 years ago, I keep for sentimental reasons (only thing I ever won, ha ha). It would still work with a converter, but there are no small Digital converters. I tried it with a convert and it worked well. Cheers

6578. Using Loop Calculators???

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-06-16 04:25:30 UTC
From: down3green
Topic: 6578 Message: 6578

Hello everyone,

My name is Don from N California. I'm new to amateur radio. So new in fact, the ink is still wet on my new technicians license. I'll be operating a K2 from Elecraft at no more than 12 watts. That's all she's got. QRP CW is my main interest. Minimal space brings me to loop antenna's, though the more I read about them, they shouldn't have to take a back seat to any other style, except maybe a yagi at 1 wavelength in height.

Mag loop antenna's really interest me. The file section shows at least 3 very useable design calculators which all seem to be in agreement with each other. My question has to do with which antenna parameters are most important in designing a loop for a specific band. I would like to design my loop specifically for the 15 meter band or 21.1 MHz.

The more I play with these programs, the more I see that I have some control over certain loop characterisics such as loop efficiency, band width, tuning capacitor value and others. I see that there is a tradeoff here, but I wonder what my priorities should be in making the PERFECT 15 meter loop antenna.

Thanks in advance for any input you might have for this newbie.

73,
Don

Hi Don,

A narrow band/frequency use is an ideal situation for a mag-loop. The formulae for such loops is I believe based on a maximum size ... e.g. 1/10 wavelength. the formula usually specifies this. I find that constructing the loop to the maximum acceptable size works the best. As you will see when plugging in the different sizes that the efficiency and useable bandwidth goes up with circumference ... the point of maximum size (for mag-loop). The RF voltage at the tuning point will also be lower compared to a smaller size. How big (circumference) you can go will of course be limited by your personal mechanical circumstances. Another consideration is going to a lower frequency band in the future.
It is also important to make the loop as robust as possible ..... copper tubing or wide strapping works well. i used a rather large 4-6 ft dia. as I recall for 20m. I used it primarily for PSK ... and setting the tuning to the center of the rather narrow PSK band allowed operation without having to touch the loop tuning. It worked very well mounted against a wooden wall only about 3 feet above ground level. A proportionately large

mag loop for 15m would give you a pretty good CW band section on 15m.

Jim, VE3CI

Hello Jim,

The more I play around with these calculators, the more I believe I would like to maximise the loop circumference to 1/3 wavelength or 14.75'. This results in a loop just under 5' in diameter which makes it at least arguably transportable for use in the field someday. The band width is wide enough to cover my frequencies of interest with a minimum of tuning effort. Thanks for your comments and confirmation.

73,
Don

Hi Don, A full size wire loop for your chosen frequency is a mere 47Ft, 71/2 inches in circumference, and can be a circle, a hex, a square, a triangle if you wish. This can roll up into a sandwich box for portability. If you feed that with a 1/4 wave of 80 ohm twin feeder (NOT coaxial) it will be super efficient and present a brilliant 50 Ohm match to your K2. This feeder is the textbook classic "Impedance transformer" length. Just a reminder that the exact length of feedline will be taking into account the twin cable's "Velocity Factor", which is quoted by the manufacturer. If that VF is say 95, then the exact length will be 95% of an electrical 1/4 wave. An electrical 1/4 wave of wire is found from 234/f, i.e:- 234 / 21.1= 11Ft 1inch. So multiply by 95/100 for the VF shortened 1/4 wave. If you needed a longer feedline, the next available length would have to be 3 times this length, and then half wave increments each time.
For any full wave loop use 1005/f for an answer in Feet. The feedpoint impedance is always around 110 ohms with the loop held wide open. Squash it up and the impedance rises. A folded dipole is around 280 ohms. "f" is the frequency in MHz.
Right now 21MHz is in the bottom of the sunspot cycle and from here onwards, the only way is UP, so you can have 4 years of steadily improving band conditions and greater successes. Welcome to the amateur fraternity Don. Mike, G4HOL, Cornwall, U.K.

Subject: [loopantennas] Using Loop Calculators???

Hello everyone,

My name is Don from N California. I'm new to amateur radio. So new in fact, the ink is still wet on my new technicians license. I'll be operating a K2 from Elecraft at no more than 12 watts. That's all she's got. QRP CW is my main interest. Minimal space brings me to loop antenna's, though the more I read about them, they shouldn't have to take a back seat to any other style, except maybe a yagi at 1 wavelength in height.

Mag loop antenna's really interest me. The file section shows at least 3 very useable design calculators which all seem to be in agreement with each other. My question has to do with which antenna parameters are most important in designing a loop for a specific band. I would like to design my loop specifically for the 15 meter band or 21.1 MHz.

The more I play with these programs, the more I see that I have some control over certain loop characterisics such as loop efficiency, band width, tuning capacitor value and others. I see that there is a tradeoff here, but I wonder what my priorities should be in making the PERFECT 15 meter loop antenna.

Thanks in advance for any input you might have for this newbie.

73,
Don

Hello Mike,

Thank you for your reply and kind welcome to the fraternity. When I saw that you are from the UK, I took a moment to look up your call sign and discovered your website. What your are suggesting for me looks to be a variation of your multi band antenna design. I need to look it over more closely. Your diagram looks very straight forward. I don't think I have ever read about a corner feed method. Very interesting.

Mike, Don and Group,

Your advice to Don is very good but my question is re to the initial length of twin lead from the feed point. You wrote, "If you feed that with a 1/4 wave of 80 ohm twin feeder..." and I followed that OK but you mentioned something about a longer from feed point would be 3 times longer and I got lost at that point. What is appropriate for the initial twin lead from the feed point to the V-Cap and radio. I use a DX 398 previously with a sq. loop of 44 ft, thin copper wire and now a sq dipole of 15 and 19 ft at the top of my office ceiling, no twin-lead. It works up to 6+ MHz but not beyond. I need a good Loop Antenna.

I have looked at the formulas, really don't understand enough of the terms, still studying. How would a copper pipe loop of 4 or 6 feet work? How do you enter that into the formulas? What V-cap is necessary? I have a box full and cannot tell what each are in (mh??).

I'm new at this, studying loops for DX only, not TX, no license--yet, studying slowly for Tech test. I'm 64 and retired, interested in too many things.

It will work great guns as a multi band loop, but don't use coaxial feedline, I use 300 ohm slotted, as all the bands present medium impedances. 450 ohm line would do much the same !.......... Mike G4HOL

6587. Best wire for medium wave loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-06-20 14:00:24 UTC
From: canondslr71
Topic: 6587 Message: 6587

I'm looking to build a 36 inch or so magnetic loop antenna for listing to medium wave (BCB). Would like to know what the absolute best wire is for this. I currently have 3 different types of enameled copper wire on hand (the type to wind motors), #17, #24, and #30. Are any of these suitable, or do you recommand something else?

Any could work. But I would probably use the #17, just for
simple ruggedness and low resistance. However, at this
frequency, the skin effect will waste quite a bit of the
copper in this sized wire. If you were really concerned
with wasting copper, you could parallel some strands of #30
and get the same or lower AC resistance with less total
weight of metal. But the result would be a lot more fragile.

Hi,

Enameled copper wire is fine. A 36" dia. loop (multi-turn and tuned I assume) is quite large. As a consequence mechanical considerations will be first and foremost. The #30 wire is probably out of the question as it will probably not stand the strain of winding on a 36" frame. It is a toss up between the #24 and #17. You can judge which gauge will work best on the frame you are going to use. You will probably be running the wire through holes or around pegs etc ... on your frame in order to space the turns. If you can physically handle the #17 gauge wire ... then I would go with the largest dia. wire you can manage given the construction of your loop project. One way of managing the maximum copper surface while maintaining flexibility is to use 'Litz' wire ... which is a multi strand copper wire with each strand being insulated. It represents the least amount of RF resistance (different from DC resistance) per dia. x. while having the mechanical properties that are 'string-like'.

Jim

Hi,

This is an interesting suggestion. I have created my own 'twisted pair' of insulated wire (for other purposes) by putting the pair in a drill chuck and giving them a twist the length of the run. It might be interesting to put a number of parallel strands of #30 enameled wire in a drill and twisting them to create a cable. Calculate the approx. total length you might need 12' x 8 turns for example parallel 3 to 5 stands, clamp one end in a vise and the other end in the chuck of a drill. Pull taught and apply the drill creating a single strand that certainly would be strong. As John suggests, the purpose is to create the maximum amount of wire surface in order to reduce the RF resistance while creating cable strength hi hi. I would be interested in how this works out if you go this route.

There is another way to twist lots of strands together to make a multi-strand cable. I like to build up the strands by combining three wires, then combine 3 of those to make a 9 strand cable, etc. Simple twisting twists each strand which hardens the copper and stresses the insulation and makes a twist that wants to untwist.

A better (but more difficult) way is to make a tool that cranks each of the wires, individually (think three cranks linked with a block that forces all three cranks to turn at the same time), with the far end of the cable terminating in a bearing. As you twist each of the strands, the far common end turns (in the bearing untwisting each strand, while wrapping the strands around each other. Boy Scouts make their own rope out of twine, this way (which is where I learned about the method). This method also allows you to twist together stranded cables that are springy and will not stay twisted if you just put the end in a drill.

(strands of #30 will have less than half the Ac resistance of a #24 wire and about the same resistance as a #17 wire at 1 MHz, even though the weight will be about half of the #17 wire.

I can see this method would work well. My simple attempts at twisting wire confirm your observation .... too tight and it kinks ... too loose and it comes apart ... needs to be just right. I can see the explanation in that each strand is being twisted as well as being wrapped into a cable.

>A better (but more difficult) way is to make a tool that

I took me some time to visualize the technique. I assume the technique is used to manufacture steel support cables of all kind.

The figures illustrate the advantage of the technique.

The absolute best wire would be Litz wire. Lowest resistance (skin effect) and lowest inter-winding capacitance. Will give you tightest bandwidth. Probably a little more gain too. The serious crystal set builders use only Litz wire for these reasons.

USE SOLID COPPER WIRE FOR CHEAP AND EASY.

The problem with wire is the "SKIN AFFECT", so keep the gauge down to about 18 or 16 so with a single wire.

DO NOT USE BRAID or TWIST MULTI (BARE) WIRE TOGETHER (MY OPINION FLAME AWAY)

The reason is again the skin affect (google it).

The BEST WIRE (and hardest to get in a small quantity but some times you get lucky on ebay) is LITZ wire.

That is both a name brand and a type of wire. Originally I think its German invention. These are braided wires in very specific weaves, but each wire has an individual ceramic coating. You get the big wire affect, but with each wire separate the skin affect is low.

You could use the wire you have and twist up your own poor man LITZ wire. Not sure the effort is worth it. That could work. LITZ is not really expensive only that it comes in very long lengths and it tends to be special order. SO you have to scrounge around for left overs or some existing stock they have laying around. May be some one on the list has a 1000' roll of some good right sized LITZ WIRE?

However the easy cheap is big old Hardware home center solid copper wire, just don't get too large of a wire gage, 18 or 16 will do*. You don't get credit for more copper since all the signal is on the outside of the wire, the skin.

You have #17 enameled that would be fine. If you are running it in a PVC conduit you could twist a few #30's together to make an effectively larger Gage wire, say 14 gage with less skin affect than the one #17. It does have a positive affect, but how great I don't know. I doubt you would notice it with out test gear.

*I assume you are RX only? If transmitting that is a different story. I assume than you will need some min copper for the power you are TX'ing with. No comment. If TX I would use copper pipe. In fact I am making a Magnetic RX only antenna now with electronic remote tune (Kind of like the Welbrook).

Cheers George

PS LITZ WIRE ALSO HAS A BIG DRAW BACK. The only way to really connect it and make all the connections is if you have a solder pot with tight controlled temp. This will burn off the ceramic coating and make electrical connections. LITZ is MANY very small small gage wires. Heat too much you anneal it and it becomes too fragile. Not enough heat the coating does not allow good electrical contact.

I don't know about the ceramic coating on Litz wire, I have a few rolls here. The individual wires appear to be enamelled, with silk on the bundle. I don't know if this is typical.
I just use a hot soldering iron to burn off the insulation. The stuff has a life of it's own and gets tangle very quickly.
For MW receive the Q doesn't need to be so high. I've had success with any wire I've tried, though it may be a different story for a crystal set where you don't have any extra gain.

Regards, Chris

Hi,
There are two types of Litz wire insulation. Most of the older Litz wire
has a standard tough enamel coating on the individual strands that will not
melt with ordinary soldering techniques. I have found the best way to
prepare these strands for soldering is to dip the wire ends into a small cup or a
bottlecap filled with a little paint remover. Allow the strands to soak
for about 1/2 hour or so, then wipe with a rag. The dissolved enamel will
wipe right off without hurting the strands, leaving the copper clean and shiny
and ready to solder. Excessive heat can damage the fine strands of Litz
wire.

The newer manufactured Litz wire has a coating on the strands called
Soldereze. This coating will melt off the individual strands when they are hot
enough to solder. Makes soldering to this kind of wire easy and simple.
Almost all newer manufactured Litz wire has this kind of coating.

That being said using Litz wire is usually overkill for a broadcast band
receiving loop as the Q will be too high. This will make the tuning too
sharp and hard to tune and will even hurt the fidelity of the stations you are
listening to by being so sharp it will cut off the high audio frequencies
making the signal sound bassy and mushy. Even some loops made with regular
solid enamel wire include a "Q-Killer" which is a high-value variable pot or
resistor connected across the loop, perhaps a 500K - 1.0 Megohm pot. This
allows the user to adjust the Q or sharpness of the loop if the tuning is
too sharp for listening conditions.

Usually only crystal radio set builders are interested in building extra
hi-Q coils or loops for the broadcast band where every last ounce of signal
level is needed. The crystal detector again lowers the Q so the tuning
usually ends up not being too sharp.

Solid enamel wire size #16-#17-#18 is probably just about right for a
medium wave receiving loop. Some people have had good luck using silver/Teflon

stranded wire of about #16-#18 size also.

I am one of those folks who have used #16 stranded & insulated, thanks to a hamfest eons ago, for a 1 meter square MW loop. It has ten turns spaced .5" on centers with a single turn about 4" in for coupling. The tuning of the entire BCB requires a dual gang cap - an old fashioned mixer/LO type works well - but a dual 365-409 pF works better. Running #18 zipcord to the pickup loop - then to a balanced input, either my HF/PR-150 combo or a homebrew BALUN and my R8, etc, yields decent reception with a good enough Q you need a large knob on the cap to tweek it.

I've also killed the Q by hooking it directly to 50 Ohms, as well as removed said coupling loop and fed the bitter ends to a diecast box enclosed balanced jFET amp/remotely tuned (varactors) amp fed via a pair of RG-6 leads to the homebrew head (TenTec box - mini box enclosed amp - very well shielded. It also had penlights to add to the 12V lead acid battery used for receiver power as the varactors needed 16-18 Vr for minimum capacitance.). I had a speck of daytime IMD from a local daytime 50kW-er with it in the attic. Just the loop now has to be in the yard to avoid AC powerline hash & QRM.

Back in the 60's, I think even Belden wire displays had small spools of Litz wire. I know Lafayette and Allied both carried it - and even had 7" ferrite rods... I played more back then. A local ham store carried Amidon - even .33 & .5" x 7" rods - back 'in the day'. I wonder how long it's been since they carried even a 'Philmore' 365 pF air variable? I think they were $7.95 the last time I saw one! I remember picking them up at EDI in Chicago - in '69 - $.19/each! I was studying the Collins R-390A in USN ET school at the time.

Palstar has a new MW/LW ferrite loop antenna (...for receive, obviously!) check their site.

Hi,

I believe the question was in relation to the construction of a magnetic loop for reception in the MW broadcast band. By definition a magnetic loop is small (in relation to a wavelength) and has a very low radiation resistance (low efficiency). As a result the loop (whether it is tuned or not) should be constructed with 'low loss techniques'. In addition, unless special steps are taken to increase receiver gain with additional low noise amplification, the loop should be 'tuned' to resonance which provides great receiving advantage .... as well as a few disadvantages. The increased 'Q' of a well constructed tuned loop greatly increases signal strength to the receiver, narrows the bandwidth reducing general received noise as well as inter mod. noise, and in my experience it seems to make the dip in the radiation pattern narrower and deeper.

The mag loop is also inherently less susceptible to local noise due to its lower response to the electrical portion of local noise radiation. After going to the trouble of constructing a 3' loop frame I wouldn't recommend going to the electric blanket for appropriate wire hi hi. I also assume that going to the length of construction a 3' loop would indicate weak signal reception. Again, low loss construction would be in order.

However, if the desire is to provide a minimal antenna for casual listening to local MW broadcast stations .... and one is using a receiver without a built in antenna such as a communications receiver or up-scale Hi-Fi receiver then a small loop 8 to 10 inches in diameter is all you need ... or, just clip it to the electric blanket hi. All other MW receivers already have built in (and tuned to resonance) antennas.

So, if one is interested in constructing a loop to provide low level signal reception for receivers without an antenna or provide a 'boost' to the performance of portable receivers with a built-in antenna I recommend using low loss construction techniques .... and unless additional steps are taken to provide additional amplification ... make the loop tuneable .... eg that resonance stuff hi hi.

As an example, there are no more MW broadcast stations in the small community in which I live. The nearest stations are about 200 miles away in the Duluth/Iron Range area. Sitting out on the deck in the morning I enjoy listening to local broadcasting in Northern Minn. and Wisc. Without

the addition of a tuned loop sitting on the coffee table (giving my receiver a signal boost) I wouldn't be able to copy a single station .... and I am certain wire from an old electric blanket wouldn't do the trick either hi hi.

Earlier I mentioned that a 3' loop was pretty large. The loop on my coffee table is a little more than 1 ft square .... I just shuffle the loop and radio around a little for best reception (minimum noise and best coupling) and then the stations 'pop' out of the background and drop back into the background as I tune the loop through their transmit frequency. Even after using the technique for years I am still amazed how the small wood frame, wire, and capacitor can be so dramatically effective. When a friend drops over for coffee (non radio type) they always think there is more to it and can't believe its coming directly from Duluth hi hi.

Each to his own ... in my case if I want to hear anything with my portable MW receiver I need a tuneable loop .... and demonstrates that tuning is critical.

P.S. I can also hear the stations pretty well on my communications receiver down in my Ham station (which is connected to a dipole 60 ft in the air) ... but not a whole lot better than my portable on the coffee table out on the deck.

Jim

My MW BCB loop is made from old TV coaxial cable. It's just 25'-30' of cable wrapped twice around a closet door as a frame, so the dimensions are... whatever the size of the closet door is.

The basic design was taken from Joe Carr's "Receiving Antenna Handbook", and I've seen similar designs elsewhere on the web. Nothing fancy but it works. Just check around for any of the diagrams featuring a shielded loop with a small break in the shield.

It deviates from most MW loops in one way - no tuning capacitor. I tried it first without a tuning capacitor (which I already had handy, cannibalized from an old radio), just as a test. It worked well enough that I left it as-is.

Covers the MW frequency range and HF up to 10 MHz, with significant attenuation beyond approximately 7000 kHz. So while it's useful as an all purpose antenna, this passive loop is pretty much limited to fairly strong shortwave stations, not for DXing. But it's much quieter than most indoor antennas I've tried for shortwave.

Using a closet door as a frame helps make it somewhat directional. Just open or close the door. It works well enough to separate XEEP in Mexico on 1060 from WLNO in Louisiana (I'm in Texas). On shortwave it's not directional in terms of receiving signals, but adjusting the door can help minimize the effects of locally generated noise. I'm in an extremely noisy semi-urban area so this is important. Between flickering streetlights, neighbors with appliances, bad powerlines, etc., other antennas pick up too much noise and are painful to listen through, even on MW.

Below approximately 1000 kHz, my portables with internal ferrite antennas beat the loop. Above that, the loop, connected to a Palstar R30C, beats either of the portables (Magnavox D2935, Sony 2010). Helps a lot when trying to separate KXTR in Kansas City from the crowd of same-same-sports cluttering 1660.

> I'm looking to build a 36 inch or so magnetic loop antenna

Here are some ideas --- my former employer was throwing away spools of 24 guage solid hookup wire. I used some for a couple of loops and found - to my surprise I might add - that the resulting loops were very selective! I've gone to no spacing between wires, it seems to boost the Q of the loop tremendously.

Radio Shack used to sell an outdoor shortwave antenna kit that had about 70 or 80 feet of Litz wire. I got one in the late 90's and used it in my backyard. Unfortunately, the Florida climate soon corroded the wire out. But - this could make a readily available source of Litz wire.

I do not recommend doorbell wire, because I haven't had much luck making high Q loops out of it, but they have all been spaced out between turns. Perhaps put tightly spaced, the Q might go up. Doorbell wire comes as a twisted pair, it is a fair amount of effort to separate over 100 feet, but when you do you have enough for two loops.

I've heard of some people using outdoor landscaping light wire for speaker wire and for loops. Pretty smart, because you can get large guage 16 or so relatively inexpensively.

Some people have even used monster speaker wire, but they find they have to put resistance in parallel because the Q is too high!

Sensitivity of a tuned loop ..... or how well it manages to transfer signals to the receiver .... either through mutual induction or via a link coil ... depends first on construction .... that is how high the circuit 'Q' .... and second the size .... the capture area. A well constructed High Q tuned loop 1' square with adjustable coupling could outperform a poor quality, low 'Q' loop 3' square even though it, the 3' loop, has almost 10 times the capture area.

However, a 3' tuned loop constructed with reasonable care will run circles around the smaller commercial loops on weak signals. If the signals are relatively strong ... e.g. you can hear the stations without the loop ... then the difference between loops will not be noticeable as the receiver AGC will make up the difference. A 3' loop is a bit awkward to use and works best on signals that you can't hear at all on the receiver without the external antenna.

For example. If I use a receiver of average sensitivity with a 1' loop I can bring 4 daytime distant stations in at a comfortable level. If I use a more sensitive receiver (SRIII) with the same loop I can pickup 2 additional distant stations (the first 4 stations aren't improved very much). However if I use the SRIII receiver and a 3' loop I can add 6 or more additional stations ... not all at a comfortable level but identifiable. However physically the 3' loop is difficult to use. The result is large loop only comes out for special occasions hi hi.

Jim

From: airchecklover
Topic: 6587 Message: 6607

I built a 3.5 ft.8-sided loop from PVC. It was big and awkward and was not leaps and bounds better than a 2 ft. square MTM Scientic loop - except as Jim points out on the incredibly weak signals. So I scrapped it and the wire is now outdoors as an end-fed sloper. The 2ft loop about equals the CCrane T-F (I also have) but doesn't require batteries and has no cables. The Quantum probably will not be beat from what i've heard and read but it is not cheap. Magnetically coupling the loop to the T-F head and the T-F direct to a good radio gives almost double the gain of either antenna alone (with good S/N) and playing the loop against the T-F head, cardoid nulls are achievable. I can get 100% quieting on either of two stations on 570 daytime. They are about 30 degrees apart.

Mark

Ya'akov, you might want to "go the extra mile" and calculate the actual (verses theoretical) efficiency of a small loop. Since the radiation resistance is so minute, you need to consider the resistance of the metal out of which the loop is constructed and consider the percent loss. You may calculate the actual radiation efficiency using a small loop calculator program. My favorite is called, loopcalc.exe, which you may download here: http://www.standpipe.com/w2bri/software/

You will find that a small aluminum loop (the MFJ loop) is less efficient that a similar size and diameter small loop made of copper.

Hey everybody,

First off, thanks again to everyone who took the time to offer suggestions in planning my new transmitting loop antenna. Since then I have read every internet link I could click on and even have a copy of "The Practical Antenna Handbook" for reference. There seems to be a lot of conflicting information out there, usually in the form of anecdotal evidence. I did find a research document which corroborated using 1/3 wavelength maximum for the circumference and decided to go with that. A metal fabricator is rolling a copper loop for me using 1.625" OD Type K (heavy) tubing into a 56.34" OD loop. For ease of shipping, two half loops will be made. I may choose to weld the pair together after I experiment a little, but for now, a silver solder joint should be adequate.

Once my loop is together, how do I proceed? I should think that I would need to determine the self resonating frequency of the loop? All the literature agrees that a mag loop's useable frequency should stay below that point. This is where I get a little confused. Confused nothing, I'm stumped :-))) An antenna analyzer is bound to be required here, yes? Thanks in advance for any input.

73,
Don

Interesting. Since the best conducting metal is actually silver, perhaps silver plated copper would be a sterling idea.....forgive the pun. The bottom line though must be: "Would it make any detectable difference whatsoever at the receiving end?" I don't think so. G4HOL

The MFJ-259B is a great antenna analyzer to use for testing a transmitting
loop. It will tell
you the resonant frequency of the loop as well as be a big help in
adjusting the feedpoint
match to the loop. I use a gamma match to feed my loop and the MFJ-259B
will tell you the
optimum length and spacing to make the gamma match for a good 50 ohm match
to the feedline.

Also you will want to decide on the best high-voltage low-loss capacitor to
use for tuning
your loop. In my experience the trombone-type copper-tube sliding capacitor
using Teflon sheet
for insulation is the easiest and best capacitor to build and use for the
money. Others have used
vacuum variables but they cannot normally be welded to or soldered to
without heat destroying
the capacitor so they end up being a clamped on connection to the loop
which reduces their
advantage in the first place.

Other than the size and quality of the tubing used the capacitor is the
second most important
component of the loop. It can make or break the total performance of a
transmitting loop.

Thanks for your reply, Todd. It happens that I was looking at an MFJ analyzer just today. I think I'll have to order one soon.

I agree that a good capacitor is a must when building a mag loop antenna. Max-Gain Systems has the Voltronics Corp. model NMT70 6E vacuum variable capacitor. It is specifically recommended for QRP operation using mag loops. The price is right at $39. I have a couple of these on order. I will be operating a 10 watt Elecraft K2.

Up to now I had been considering using a Faraday loop to energize my antenna. Did you have a reason for going with the gamma match instead?

This unit works
Time owned: 3 to 6 months
I'm a firm believer in "if I need a tool that I will reuse, I buy the best I can research and find" - this unit fits the bill. Using this on my IC-756ProIII with a Hi-Q resting on a tripod. The battery seems to last for ever, but we all know that it needs to be charged eventually. I'm getting 160+ runs of analysis on a single charge. You wont be disappointed.

Perfect for Buddipole
Time owned: 0 to 3 months
I purchased my AA-200 at the 2009 Dayton Hamvention for the primary purpose of tuning and adjusting my Buddipole portable antenna. It is perfect for that purpose. Although more expensive than the MFJ-259B that I previously used, the AA-200 is faster, easier and more enjoyable to use for this purpose. I highly recommend it to other Buddipole owners.

Thank you. I have Turbo-Pascal (Legally) for MS-DOS so there
should be no problem getting it to work on my computer(s).

I still wonder why even a hand calculator is needed to figure

R=19246*((D/L)**4)

R is radiation resistance in Ohms
D is diameter of circular loop
L is wavelength in same units as D (if D in meters, L in meters)
* is times
** is to the power of in ForTran, symbol ^ in Basic

For elaboration on this Formula and my research, refer to

http://members.shaw.ca/yehudi2/loop.html

When I went to school, I was only allowed to use a *slide rule*
after I had demonstrated basic arithmetic skills, and also
convinced the teacher that I knew how to use a slide rule.

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.

Palomar?s Loop Antenna gives superb performance on the AM medium-wave broadcast band. The
loop rotates and tilts to give deep nulls so you can eliminate local interference. It also
allows you to null out a station and listen to another one on the same frequency.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

6627. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-07-01 13:33:02 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6627

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

6630. My 6m - 80m magnetic loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-07-01 18:52:04 UTC
From: mwsmith65857
Topic: 6630 Message: 6630

I've been playing with loops a bit and put together a reasonably successful one with 32' of wire made into an 8' square and hung off a fence. From the lofty altitude of four inches, I made a contact into Venezuela, and worked stations across the states.

So, I figured I had to refine my design a bit so I could take this thing to field day. First off, I needed to get away from a square, for efficiency's sake. A circle would be best, but difficult to build and easily transport. An octagon was the next best choice. Also, it had to be made out of PVC, just for ease of construction, strength and availability of materials.

Cruising the internet one day, I saw this loop design:

http://www.arrl.org/news/features/2008/02/05/1/

That was exactly what I needed for the basis of my loop framework. I simplified it, and got rid of the convoluted sections (although that might go in later for experimental purposes) and rigged one up.

My loop ended up 9.6' across and is tuned by a Icom AT-2 coupler. I'm driving it with an IC-706MKIIG, at 100w. On field day I worked 25 states with it in a 21 hour period from Katy, TX, including one on 15m out to Hawaii. That's 3,700 miles from an antenna about 2' off the ground, not too shabby! :)

I've posted pictures of what it looks like in the photo area.

http://groups.yahoo.com/group/loopantennas/photos/album/2130309806/pic/list

I would have posted the pics inline, but I'm not exactly sure how to do that, haha!

Next steps include:
1. See the effects of reducing the diameter by increasing the turns
2. Mount it on an antenna rotator so I don't have to run out to the back yard to spin it.
3. See if the convoluted design works for this type of antenna, which would hopefully allow me to reach 160m, and also be more efficient on the lower bands

So it occurs to me that possibly my loop isn't a magnetic variety since it's not magnetically coupled with a Faraday loop? Not sure. I was under the impression that anything under a full wave loop qualifies as a magnetic loop, maybe I am mistaken.

Any guidance is appreciated!

Ok, so last night I decided to shrink the loop. I went from the monster 9.6' diameter to a 3.2' diameter. This meant I went from a single turn loop to a three turn loop. Results? Well, it works just fine. Still tunes up from 6m to 80m. Had a good long QSO with my dad (who lives just a couple miles down the road) and he said that my signal was the strongest it has ever been, so that's something to get excited about. I went from S7 to S9, and that's a pretty significant improvement. I'm going to post the new picture of what it looks like in the photo album that I linked earlier.

So, now the plan for the weekend is to rehabilitate an old HAM-M rotor to work with this antenna. More turns = more directivity, so the rotor becomes more important. Nice thing is that I think I'll be able to shrink this down nicely to fit in the attic, and have a rotatable antenna up there without anything exposed that might freak the local HOA out.

I'll keep y'all posted with results from this weekend.

Hi Michael,

What polarization is your Dad's antenna? If the antenna is operating in a electromagnetic loop mode, the antenna is going to be horizontally polarized, fed from the bottomm, vertical fed from the side, when the plane of the loop is vertical. Such a loop will have pattern nulls in the plane of the loop along the horizon. If the antenna is operating as a magnetic loop mode, and again the plane of the loop is vertical, the antenna will be veritically polarized, and have a peak in pattern gain in the plane of the loop.

The shape of the wire has an effect. If its a coiled shaped, then the loop will be magnetic when the circumference of a winding is less than .125 wavelength, I believe. The extra wire acts to increase the inductance of the antenna.

If the wire is in the maltese cross shape as the wire gets longer characteristics will transistion to that of a folded dipole, and then to that of a full wave loop. Here the transmission line shape of the wire will create capacitance in the winding. If the length of the wire is longer than about .25 lambda, electrical effects are most likely happening.

There is a practical difference. At low frequencies you may get allot of heating in your tuner. As the radiation resistance of the radiating element are very low. So, the loss

resistances in the tuner become a much greater fraction. Or in other words, the current is so high in the element (as the radiation resistance is so low), that being in series the losses in the tunner have a much higher I^2R losses.

Don,

Thanks for your response! My dad's antenna is a trapped dipole, which is horizontal.

I just posted a recent pic of the antenna outside during the daylight. Much easier to see what's going on like that. Here's a link: http://groups.yahoo.com/group/loopantennas/photos/album/2130309806/pic/566933347/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

The circumference of the current loop is ~10', but since it is 3 turns, the total wire length is 32'. Not sure if I'm just repeating what you already know here. :) I do know that the tuner tunes it very fast on 10m, it gets slower and slower as I go lower. 10m seems to be the sweet spot, as 6m takes quite a while too.

Very interesting comments on the maltese cross setup. The great thing with this antenna design is that it is very flexible where experiments are concerned. None of the radial arms are glued, they are all held in by the loop itself. I can swap out from long arms to short arms and anything in between. I may try the maltese cross thing, as all I'd need to do is buy some more tees and a set of 1/2" PVC crosses and then weave the wire in between them. The toughest thing is going to be calculating what length to make everything so I can end up with an complete turn at the end!

I agree with you on the lower bands and the low radiation resistance. I know it's not very effective on 80m, but it seems to do ok on 40m. 20m and up is a walk in the park.

All in all, very exciting times here. :) I'm hoping I can end up with something that will fit nicely in the attic and be relatively inexpensive to acquire.

Hi,
The ' Maltese Cross ' format sounds like the Pfeiffer Quad in QST
some years back, an excellent antenna ???
Just a thought.

Yep, the article that I read in QST cited the Pfeiffer quad as inspiration.

Was pressed for time yesterday, but was able to make a contact on 17m to Virginia yesterday, so that was ~1,000 miles. QSB got the better of me, but the other fellow was fading too. Got tied up in the restoration of an old HAM-M rotor, so didn't get a chance to log any more contacts. 10m was open yesterday too!! Doggone it.

Hi Michael,

The kind of loop you are describing is not what is generally known as a 'magnetic loop'. It is a loop alright. the SGC company who are known for manufacturing automatic antenna couplers marketed what they called an all band 80-10m 'stealth' antenna which consisted of 80' of antenna wire to be formed into a loop of 1, 2, 3, or 4 turns ... depending on local physical opportunities. the antenna could be tuned/matched/coupled with one of their antenna couplers at the feed point and feed the xcvr with standard 50 ohm coax. For normal operation the antenna works best 1. as a single turn loop 80' in dia. and 2. the higher you can mount it the better.

The lower you mount the loop the higher the angle of radiation and the more turns you put the smaller the capture area.

Now, you can counter-act the effect of reducing the capture area by making the loop high-Q ..... which basically makes the loop a small (1/10 wavelength or less) at the frequency of operation and tuning it to resonance .... employing 'low-loss' construction techniques ... generally referred to as 'magnetic loop construction'. This of course immediately makes the antenna not only a single band antenna ... but also gives it a narrow band-width. It takes a lot of complicated electro/mechanical manufacturing to enable 80-10m operation.

Getting back to the kind of loop/antenna you are describing it is basically taking a standard antenna and using techniques to reduce it's physical size. There are myriad ways to shorten dipoles or loops ... using multiple turns (in loops), using folding techniques, stubs, etc. .... P.S. "more

turns = more directivity" is not very well founded in fact hi hi .... in fact it can be the reverse.

Let's take an example ... a loop 70' in circumference (naturally resonant in the 20m band). Mount it vertically on a tower 70' above ground ... and you have a dynamite antenna ... it is efficient, low angle of radiation, broadband (but effectively tuned 40-10m if you wish ..... and quite directional (front to side ratio) at or near to its natural resonance frequency. Now lets compromise ... lets take the original loop 17.5 ft per side and form it as a 3 turn loop 5.8' per side. The natural resonance will be lowered considerably due to added inter-turn capacitance .... however it could be easily matched with open wire line and a balanced antenna tuner .... or an SGC antenna coupler at the feed point fed with coax. It will still be an effective antenna although the antenna gain will be down considerably and the radiation pattern will be less directional (much less defined front to side ratio) ... but still generally broadside to the loop. The vertical angle of radiation will still be very good as it largely a function of height above ground.

Now, take the same antenna (3 turn loop 5.8' per side) and mount it against your wood fence 1' above ground and you will find that it becomes near vertical in its radiation pattern and totally ineffective to communications at a distance ..... although it loads quite nicely with the antenna tuner .... and the front-side ratio will be barely detectable.

Unfortunately bigger and higher (especially higher) really counts.

Jim,

Thank you for your comments. They are definitely appreciated!

I did look at SGC's stealth book, and that's where I realized I could put multiple turns in the loop. The only adjustment I made was to use the lengths suggested by the AH-4 tuner spreadsheet, and 80' was right at a "bad length." I was looking (initially) to make a single-turn loop, so 32' was about as big as I wanted to go and have it fit somewhat nicely in the backyard.

Interesting what you say about multiple turns not necessarily getting more directional. I'm restoring a HAM-M rotor, so within a week I'll be able to see how much spinning the thing makes a difference. I do think that the multiple-turn loop does lose some gain though. Everything seems a bit more quiet than I've been hearing lately. This falls in line with your "smaller capture area" comment. Sometimes hard to tell with changing band conditions though. I can swap back and forth from single-turn to triple-turn easily, but the change probably takes 30 minutes to reconfigure...not much good for an A/B test! I will say it's likely it's a high-q type setup. 3.2' connected directly to the tuner. After a tune cycle, the noise level definitely goes up, so it's working in that respect at least, hi hi.

Funny you mention the fence-mounted antenna. I built one of those. It was an 8' square, mounted somewhat off of vertical, probably about a 20 degree lean. One single loop of wire, 32' long. I had it strung from the fence to the wooden deck, so that put it right at about 4" off the ground. I worked Venezuela on 6/4/09 on 17m with that setup! I was pretty surprised it got out that far. Signal report was a 44, but still, pretty cool stuff.

On my 3.2' loop this afternoon, I worked Puerto Rico on 17m and got a signal report of 55. That one is about 5' off the ground. That honestly surprised me. He came back to me on the second call.

So, I've got a bit more experimentation ahead of me. Going to work this small loop for a while, see how it goes. Need to play with the rotor, see how that may improve stuff. Next will be playing with the maltese cross stringing of the wire, that may reap some good benefits too, if the less turns=more capture area holds true. Definitely worth a try, and easy enough with PVC.

6640. Loop on house roof?

Yahoo group: loopantennas (2008 — 2012)

From: Bill McGraw
Topic: 6640 Message: 6640

I'm still new about loops and very weak on the electronics parts, still can follow some of it. I cannot climb a ladder or put up a tower but might get someone to put a loop on my roof or roof to shop to patio and back to my window. I cannot get into my attic anymore, too weak to climb the damn ladder.

How would TV cable work as a 21 foot diameter (66 ft circumference) loop on a slanted roof for 80, 40 and 20 Meters? If it would work, how should it be fed into a receiver? I only have several V-caps and a RS DX-398 and a shallow ground, no other equipment, no antenna tuners other than the several V-caps.

I really don't want or have room in my "office" for any other equipment. It is full of computor equipment, 3 desks full of stuff, guns and my "gunsmithing" working desk where I fix anything needs fixing.

Or I might be able to run the TV coax from my roof to my shop about 30 feet away and from there to my patio roof, another 25 feet and back to my roof, another 10 feet for a rough triangle of about 65 feet, really needing about 66 ft if the formula is correct for 15 MHz, the highest frequency. Does that sound right?

If anyone could offer an explanation, be graphic in details about running any connections from the antenna and to my receiver.

Hi Bill,

I take it you want to use the loop for receiving SW broadcast and other signals on your DX-398 receiver. The kind of loop you describe is more or less full-size ... and not a tuned small loop. You will not need a tuner or your v-caps. You will have more than enough signal for your radio without precise tuning or matching. You mention laying out TV cable as the antenna .... a good choice as it is insulated and should do good service over a long period of time. You will treat the whole cable (shield and center conductor) as a single conductor. I would not worry about exact length ... you mention 66' which indeed is approximately resonant at 15mhz and present a reasonably low impedance value at the feed point which can be fed with another length of TV cable as the feed line. It would be best

from a physical point of view if your cable is terminated at each end with a TV connector. I would simply use another piece of standard TV cable as a feed line. The project would then be to layout the first length in a more or less circular pattern so the two ends are almost together. At that point (feed point) place one end of the second piece of TV coax (feed-line) with the other end at your listening position .. next to the DX398.

The trick will be to fabricate an appropriate junction at the feed point of the loop and at the receiver. At the loop feed point you want your junction to make a connection between the shield of the feed line with one end of the loop .... and ..... the center conductor of the feed line to the other side of the loop feed point. Then, at the receiver you will have to fabricate a junction that will connect the end of the TV feed line to the connector on your RS DX-398. There are various TV cable hardware adapters available and you will have to use your imagination and mechanical skills to manufacture the two junctions (at the loop feed point and at the receiver). Be sure the junction at the feed point (on the roof) is weather proof. The antenna will provide all the SW signals your receiver can handle without any tuning required.

If you were planning to transmit with the loop then other strategies would have to be employed which would more precisely match the impedance at the feed point to the feed line and more precisely match the feed line to the radio for maximum efficiency. However for SW listening these mismatches are of minor concern and your radio has more than enough gain to compensate.

More likely they are variable capacitors under a vacuum. Sometimes this
can be in a glass tube or metal case. Google search is your friend and
will bring up many images.

The more I googled, the more confused I got, so I popped over to the electronic workshop and asked the techies there. The consensus was that v-caps are probably vacuum variable capacitors although one quiet dissenting voice offered that they were perhaps voltage controlled capacitors. Then the senior technician walked in and stated boldly and unequivocally that a v-cap is any variable capacitor with vanes which I guess excludes the vacuum variable capacitor as that uses cylinders instead of vanes.
I think I will just avoid the term :-)

Cheers, Chris

An update from this weekend's operation.

First off, small loop = poor RX. It goes back to capture area, just like Jim said. I just wasn't hearing what I heard before with the 9.6' loop. I switched back to the large loop and heard the stations I was missing. The bands just sounded absolutely dead with the small loop.

With the small loop, TX is as good, or better than the large loop. This was confirmed with a short-range contact. I figure that comes from the small loop is easier to keep one loop diameter off of the ground. The large loop can't measure up on TX because it's only about 0.25 dia off of the ground. I just lose too much into the ground, and that's even with a much better power supply!

What it seems like to me is that on TX, coiling the loop just doesn't matter. Wether it's 3 turns or 1 turn, you're going to get out the same. The big difference is on RX. It feels as if even though it's 32' of wire coiled 3 times, it feels like a 3.2' diameter loop, or 10' of wire around the perimeter.

So, the small loop is out. Just not worth a darn on RX. The big loop (for backyard use) is out, because it's just too big. Too big to take up and down every day, and way too big for the Homeowner's Association to ignore. Just one of those things you have to deal with when you live where you want to live. (That means "Move, stupid!" is is not an option!)

So the next step is to go the route of the convoluted/maltese cross loop ala W7PTL and K1KLO (the originator.) A bit of math shows that I should be able to weave 38' of wire on a 4'4" diameter frame. This will all be with a single-pass of wire, so I shouldn't feel (as much) the loss of capture area. If so, this could be a really good thing, and I might even be able to fit it into my attic.

Hopefully the motor start capacitor will get here for my rotor, and I can play with this a bit this weekend. I sure am glad I got the PVC snips instead of relying on a hacksaw! I can't tell ya how many feet of PVC I've run through already...maybe 40' or so?

It's pretty easy with an antenna coupler and some wire. 40m and 20m will come easy, but to be efficient on 80m, you're going to want to go as large as you can.

I must take exception to small loop = poor RX. What matters on
receive is the SIGNAL/NOISE ratio, not the absolute SIGNAL value.

To prove my point, I have beside me a "Playmate" AM-only broadcast
radio. It tunes from 600 meters down to 200 meters (0.5 - 1.5 mHz)
The loop is really tiny, many turns in a coil about 1/2 an inch in
diameter, wound on a ferrite rod. The radio receives "real well"
and I have heard all over the United States at night, when the
ionospheric "D" layer with its absorption is absent. Since the
antenna is a small (much much less than a wavelength) magnetic
(ferrite is magnetic!) loop, it is directional as h-ll, and I can
rotate the whole radio (thereby rotating the loop) to null out
any noise sources.

If I want a loop which is efficient as a radiator, I am interested
in its EFFECTIVE capture area, not its actual size. A simple
calculator for the radiation resistance of a one turn circular
loop which is 0.1 wavelength or smaller is given in this link

http://members.shaw.ca/yehudi2/loop.html

One such antenna is a yard (about a meter) in diameter, and is
capable of working from 40-15 meters. It is manufactured by
MFJ enterprises, uses thick aluminum pipe, and has a "butterfly"
capacitor (no sliding contacts for contact loss). The transmitter
is "coupled" into the loop by a much smaller "parasitic" loop,
and the circulating current in the bigger (yard diameter) loop
is of the order of tens of amperes. Adobe acrobat of Manual is at

http://www.mfjenterprises.com/man/pdf/MFJ-1786.pdf

and the antenna in question is actually an MFJ-1788 - to order

http://www.mfjenterprises.com/Product.php?productid=MFJ-1788

On 40 meters the radiation resistance is about 1/100 of an Ohm, so with the circulating current being of the order of 100 Amperes, the radiation resistance is of the order of 50% or greater. Note that to have this much circulating current, the "Q" or quality factor must be very high, and the antenna is very low bandwidth. Please read the Manual for more details...

I have one on order. I will mount it indoors in my wood frame ground level apartment, vertical plane, and report back how it works out. In passing I should note that the Loop is Magnetic, and the Magnetic field does not transform into a Radio Wave until a distance of about 1/3 of a wavelength, so it is relatively immune to (electrostatic) noise sources closer than this distance, which works out to about 50 feet on 40 meters. Ideal inside, and because of reciprocity, it won't couple into most electronic items that we Amateurs frequently interfere with, such as unshielded amplified speaker leads which sense Electric, not Magnetic fields.

Ok, you can take exception if you like. :) If I can't hear any signals in the noise, it's not a good RX antenna, plain and simple. What really matters on receive is . . . can you hear the stations?

All I can tell you is that with the smaller loop, I only heard 1 - 2 stations. Once I switched to the large one, I heard more than I can count. Could band conditions changed in the 30 minutes it took to reconfigure the antenna? Sure. Could all of the bands changed equally remarkably, possible, but not probable.

I was listening to one station around LAX that I was trying to contact. I heard him talking after he signed with one guy as if he was working a pileup. I could hear nothing of the other stations. Once I switched to the big loop, and heard him call again, I could hear about 6 stations calling him. That made it pretty clear-cut to me. Sure, there can be other reasons for it, but it would be a pretty big coincidence I think.

I'm familiar with the MFJ loop. I'm also familiar with the impressively high price, and the tendency of the tuner box to self-destruct. No need to run an informercial about it for me, ahah! I've already evaluated it and discarded it as a solution. Maybe if I find a used one at a hamfest for ~$100 I might give it a try.

I'm a bit confused on how you're relating capture area to TX effectiveness, maybe you're thinking more about RX? As I stated before, my small loop (3.2', or 0.97m) works perfectly fine for TX. Electrically, it still tunes like it's a 9.6 (2.92m) loop. Since it's just a coiled inductor, electrically it's the same length, even those physically it appears smaller. My 2,000+ mile contact to Puerto Rico proved that.

I would be very interested to know a side-by-side comparison of the MFJ loop RX to a dipole. If the MFJ is able to pull in the same signals at the same signal level, then I'll rethink how I think about small loops. Yes, I realize loops are quieter, but if the signal level is so low you can't hear it, even with the low noise level, it's not much good now, is it? You can use a preamp to increase the gain, but then you're also adding more noise to the signal.

In closing, please watch your tone. I realize you may be very passionate about what you are doing (particularly since you dropped $400+ on a new antenna) but there's no need to talk to me like I just fell off the turnip truck.

73,
N5TGL

Very true. I often hear people spousing "reciprocity" between receiving and transmitting with the same antenna. Designing an antenna for receiving is different to designing an antenna for transmission. One just has to look at the AM reception with the automobile radio. I would hate to estimate the capture area of the 3' whip ... let alone modern 10 inch antennas common these days. However they demonstrate excellent MW broadcast reception. If I locate in quiet area ... like a park .... I can receive weak daytime MW stations with the same efficiency as my portable with the assistance of a small tuned loop (sitting on the park bench).

Of course when you move into town ... local RFI makes the small tuned loop superior by virtue of its ability to null the noise while the 10 inch whip on the car (parked in the drive) becomes useless.

Small antennas are infinitely interesting and provide very specialized and surprising results.

Getting back to capture area of near full size antennas. I recall reading the results of tests performed by a recognized antenna guru on doublet/dipole size vs gain. The results were very surprising (to me) ... in that they indicated that the difference in efficiency (gain) of an full size (1/2 wave dipole) and one reduced in size by half was only a couple of DB. In other words the gain of a half size doublet 16 ft in length at 20M is down only a couple of DB from a full size 1/2w dipole 32 ft in length. However, the problem is coupling a feed line to a shortened antenna is difficult when delivering RF power is the objective.

The example above demonstrates that using a 16 ft dipole for 20m is a different problem for transmitting than it is for receiving. It is a different problem getting power into the antenna effectively than it is to get received signals into a high gain receiver effectively.

I have a rotatable dipole 42 ft in length that I feed with open wire line 40 - 10 mtrs. I have no difficulty feeding the antenna up to 100w on all bands using 450 ohm ladder line. I started out with the antenna being 32 ft in length and feeding it on 40m was touch and go and it was only possible to feed about 20 watts. Adding the 10' of electrical length greatly improved the efficiency and full 100 w power is achieved with reliability. The added 10 ft increased the efficiency not due to increased capture area, but brought the feed point impedance at 40m into a reasonable range for the feed system.

Reducing the capture area does reduce gain .... but on a rather slowly declining slope. For receiving the decline is compensated for by the receiver gain. When the antenna becomes really small (vis-a-vis) a wavelength then surrounding noise becomes the problem and the antenna design strategy must be directed at increasing the signal to noise ratio. If the small antenna is to be used for transmission of RF power then the design strategy is to maximize coupling efficiency.

Designing antennas is a non ending battle of picking design strategies to meet circumstances and objectives.

Please allow me to point out that there is a more important
virtue of a loop MAGNETIC-sensing antenna over a whip ELECTRO-
STATIC-sensing antenna. For a distance of about 1/3 of a
wavelength (from my University Honours degree in Physics) the
STATIC fields (+ the INDUCTION fields) are WAY stronger than
the RADIATION (= RADIO WAVE) field. Thus at distances shorter
than 1/3 of a wavelength (about 500 feet at the upper end of MW)
MAGNETIC-sensing LOOP antennas do not HEAR electrostatic noises
(such as from TVs, Computers, Electric Motors, etc.) very well
if at all. This is quite INDEPENDANT of the fact that a
magnetic LOOP antenna can null out noise if oriented correctly.

Thus my "PLAY-MATE" AM Radio (1500 - 500 Meters, 0.5 - 1.5 mHz)
does not HEAR most domestic (and industrial) noises closer than
500 feet at the Upper end (1.5 mHz) and 1500 feet at the Lower
(0.5 mHz) end of the MW AM Radio Broadcast Band with its 1/2 inch
LOOP(-stick) diameter loop wound on a Ferrite (=Magnetic!) rod.

You have to drive your car with its ELECTRO-STATIC "whip"
antenna into the Park well away from man-made ELECTRO-STATIC

noises in order to acquire the same "EARS" as my tiny portable
"PLAY-MATE" AM-only 6 Transistor Radio with its Ferrite
LOOP(-stick) antenna can do right beside me in the ground floor
of my wood frame apartment building any time of the day or night.

Hey Michael; interesting thread. Why not use the large loop for rcv'g and the small loop for transmitting? Best of both worlds.

-Mark

> Ok, you can take exception if you like. :) If I can't hear any signals in the noise, it's not a good RX antenna, plain and simple. What really matters on receive is . . . can you hear the stations?
>
> All I can tell you is that with the smaller loop, I only heard 1 - 2 stations. Once I switched to the large one, I heard more than I can count. Could band conditions changed in the 30 minutes it took to reconfigure the antenna? Sure. Could all of the bands changed equally remarkably, possible, but not probable.
>
> I was listening to one station around LAX that I was trying to contact. I heard him talking after he signed with one guy as if he was working a pileup. I could hear nothing of the other stations. Once I switched to the big loop, and heard him call again, I could hear about 6 stations calling him. That made it pretty clear-cut to me. Sure, there can be other reasons for it, but it would be a pretty big coincidence I think.
>
> I'm familiar with the MFJ loop. I'm also familiar with the impressively high price, and the tendency of the tuner box to self-destruct. No need to run an informercial about it for me, ahah! I've already evaluated it and discarded it as a solution. Maybe if I find a used one at a hamfest for ~$100 I might give it a try.
>
> I'm a bit confused on how you're relating capture area to TX effectiveness, maybe you're thinking more about RX? As I stated before, my small loop (3.2', or 0.97m) works perfectly fine for TX. Electrically, it still tunes like it's a 9.6 (2.92m) loop. Since it's just a coiled inductor, electrically it's the same length, even those physically it appears smaller. My 2,000+ mile contact to Puerto Rico proved that.
>
> I would be very interested to know a side-by-side comparison of the MFJ loop RX to a dipole. If the MFJ is able to pull in the same signals at the same signal level, then I'll rethink how I think about small loops. Yes, I realize loops are quieter, but if the signal level is so low you can't hear it, even with the low noise level, it's not much good now, is it? You can use a preamp to increase the gain, but then you're also adding more noise to the signal.
>
> In closing, please watch your tone. I realize you may be very passionate about what you are doing (particularly since you dropped $400+ on a new antenna) but there's no need to talk to me like I just fell off the turnip truck.

Mark, Thanks for your kind words.

Good point. The problem is that I am space limited, and really only have room for one. Eventually, the antenna will go up in the attic, which will get rid of the ground loss problem, as it will be ~12' up, about 3 loop diameters off the ground. That would remove the main advantage of the small loop.

This weekend will bring the experimentation with the maltese cross arrangement. I'm going to take some s-meter readings from a known power level at a known distance to make my evaluation of performance less objective and more subjective. That will get the up and down of the bands out of the equation. I'm hoping that the RX of that loop will be a good compromise.

On another good note, I succeeded in fixing the HAM-M rotor. Had an open winding in the motor (a factory weld, no less!) and a dead motor start capacitor. Works good as new now.

From: aimo ruoho
Topic: 6640 Message: 6654

Hi, folks!

I have been fixing a "Loop" on my higher flat roof lately.
It measures about 4x4 meters in a square decline form.
I used 1.5 mm plastic covered stranded copper wire.
Total length of the wire is 8x4x4 meters, 128 m.
Distance of every round of wire is a rather exact 1",
25 mm. I had to saw 10 inch times 2.5 " sheets of thick
plastic, to which I drilled 10 holes, 2 for nylon rope and
8 for antenna wire.

I haven't as yet put any Amidon ring in between the
antenna and coaxial cable down lead, but I think, that it
might make things a little better? What do you people
think? Any way I will test it one day soon...

Although I have read a lot of this type of "folded long wire",
I doubt, that this project did not give the wonderful results,
that people have been talking about.

This "Loop" gives almost as good signal on all channels
under 30 MHz as my other antennas, which are MANY,
but not any better.

Some examples: 252 kHz- 9+15 to 30 dB
567kHz- 9+30 to 45 dB,
855kHz- 9+22 to 38dB,
1539kHz- 9+30 to 35dB
1602kHz- 9+10 to 15dB
6075kHz- 9+10 to 20dB
11750kHz- 9dB
15380kHz- 9+10dB
17745kHz- 9+10dB
and 21840kHz-6 - 9+10dB

All these tests I made on the same day after 5pm GMT,
so the last few showed an astonishingly strong
signal. S/N/N was also quite good.
I used my YAESU FRTä7700 A.T.U., which naturally helped
on almost every channel, more or less, as usual.

It may be, that I will make some more tests in the future.

Best Regards to all!

Aimo

I'm still new about loops and very weak on the electronics parts, still can follow some of it. I cannot climb a ladder or put up a tower but might get someone to put a loop on my roof or roof to shop to patio aasy steps.

Please allow me to point out that there is a more important
virtue of a loop MAGNETIC-sensing antenna over a whip ELECTRO-
STATIC-sensing antenna. For a distance of about 1/3 of a
wavelength (from my University Honours degree in Physics) the
STATIC fields (+ the INDUCTION fields) are WAY stronger than
the RADIATION (= RADIO WAVE) field. Thus at distances shorter
than 1/3 of a wavelength (about 200 feet at the upper end of MW)
MAGNETIC-sensing LOOP antennas do not HEAR electrostatic noises
(such as from TVs, Computers, Electric Motors, etc.) very well
if at all. This is quite INDEPENDANT of the fact that a
magnetic LOOP antenna can null out noise if oriented correctly.

Thus my "PLAY-MATE" AM Radio (600 - 200 Meters, 0.5 - 1.5 mHz)
does not HEAR most domestic (and industrial) noises closer than
200 feet at the Upper end (1.5 mHz) and 600 feet at the Lower
(0.5 mHz) end of the MW AM Radio Broadcast Band with its 1/2 inch
LOOP(-stick) diameter loop wound on a Ferrite (=Magnetic!) rod.

You have to drive your car with its ELECTRO-STATIC "whip"
antenna into the Park well away from man-made ELECTRO-STATIC

noises in order to acquire the same "EARS" as my tiny portable
"PLAY-MATE" AM-only 6 Transistor Radio with its Ferrite
LOOP(-stick) antenna can do right beside me in the ground floor
of my wood frame apartment building any time of the day or night.

I have a problem with the use of 'electro-static' when I feel you may mean electric field. As the E/M wave propagates, of course, it's E & H fields are never constant (Re: Poynting vector - basic E/M propagation.). The short E-field aerial is more of a 'voltage probe' - as is the short wiring to/from fluorescent lights, motors, etc, although it is a 'source'. So, the whip picks up the E-field, while the ferrite cored loop, etc, respond to H-field (magnetic).

Back in the eighties, I and an SWL friend went on a mini-DXpedition to prepare for the real thing - and get away from my local EMI source - coronal discharge on power leads in front of my home. We went into a state park - and set up at the vacant primitive campgrounds in the back of my truck using a freshly charged 105 A-Hr marine battery and his FRG-7 and my SPR-4. We ran short Beverage antennas in three directions. We were greeted with the same horrendous noise level we thought we had left at my home. The fourth direction had a pole with a pole-pig mounted - only 20 ft from our listening spot - and no loads connected. As night fell, you could see the tensioned insulators with corona - on the pole - with no loads - in the middle of no where. On the way home, the battery broke it's bungee cord securement and turned over, getting under the truck bed's pad. It was a horrible experience.

Oh yeah, my greatest honor was that I actually graduated - in physics - Auburn U. '75. I've held a First Class Radiotelephone License since '68.

John

PS The AL-4 loop on the SPR-4 didn't help - what a noise level!

Despite your Physics degree (I have First Class Honors Physics 76)
and a Post Graduate Master's Degree in Physics 78, I must differ.

For a distance of 1/PI (approximately 1/3) of a Wavelength or less
the Static Fields (Electric and/or Magnetic) swamp the Radiation

(Electro-Magnetic) Fields. Thus an Electric Probe preferentially "Hears" Electric noise sources, and a Magnetic Probe preferentially "Hears" Magnetic noise sources up to 1/3 of a wavelength from the noise source. Further than that, only the Radiation Field persists. Orders of Magnitude (Static (1/(R*R*R)), Induction (1/R*R), and Radiation (1/R)) All three fields are of equivalent strength at a distance of One Radian (1/PI, i.e. about 1/3) Wavelength away from an Electrically Short Antenna. Further than that, as you can see, the Static and Induction fields quickly DIE AWAY.

For a probe to be truly Electric or Magnetic, its dimension must be less than about 1/10 (0.1) of a Wavelength. The loop(-stick) antenna that is 1/2 inch in diameter and wound on a Ferrite (Ferrite is Magnetic too!) Rod on my Six Transistor "PLAY-MATE" AM radio is much much less than 200 feet (1.5 mHz) or 600 feet (0.5 mHz) so it is a true Magnetic Probe, and will NOT PICK UP the Electric field, in PARTICULAR the electric STATIC field and the elecric INDUCTION field from an Electric Noise Source.

Here are a few jewels from W8JI on this topic.

So much for the myth that a receiving antenna can sort good signals from bad signals (noise) by virtue of being "magnetic"! We not only don't have the field response we might have imagined, we also almost certainly have no idea if close-by unwanted noise or signal sources are radiated from electric or magnetic field dominant sources. Successful noise reduction by virtue of by antenna "style" would mostly be a matter of hitting a lucky combination through experimentation.

Field impedance noise rejection is probably one of the deepest rooted falsehoods in amateur and SWL receiving.

An example: a decade ago I lived in central Oregon and
enjoyed the 22:00 hour of old time radio shows broadcast
over KNX Los Angeles 1070. Someone in the apartment
building apparently had some kind of light dimmer, judging
by the huge radio noise on the MW band. I was using only
one receiver, a Panasonic RF-2900. Unlike most portable
MW/ SW/ FM radios, this one kept the whip antenna connected
when switched to MW band - most radios disconnect the
whip and use only the ferrite core stick on this band.
I found that due to the noise level I could not actually
listen to the broadcast. What I finally did was to run a
Radio Shack alligator jumper from the whip antenna to an
exposed metal trim on the radio, a metal contact that also
contacted the radio chassis. This effectively shorted out
the whip antenna, and made the unusable signal actually
listenable.
Another noise minimizing idea I once read in a 1930s
Short Wave Craft magazine: the antenna was a dipole, fed
by some kind of twisted balanced line. There was a pot
at the receiving end, with the wiper grounded. This was
adjusted for best balance. The article claimed this could
worthwhile minimize noise. I think for use with coax you
would have to use twinax or use two coax cables with the
shields bonded every so often. -Hue Miller

I must disagree with you there. Let us consider a permanent magnet.
It has a magnetic field (I think you will agree), and if it is not
moving, there is NO ASSOCIATED ELECTRIC FIELD. Low Frequencies
approximate a DC permanent magnet, so there is a STRONG magnetic
field close to the (Magnetic) antenna, and only a very WEAK
electric field close by. Q.E.D.

I have a Batchelors (Honours Physics 76) and Masters (Physics 78)
so I think I can speak with some authority on the following:

All antennas have three fields, the Static field, the Induction
field, and the Radiation field. The Static field falls off as
1/(R) with distance, the Dynamic field falls off as 1/(R*R) with
distance and the Radiation field falls off as 1/(R*R*R) with
distance R. At a distance of 1 Radian (1/PI) of a Wavelength, all
three fields have equal value. As you can see, closer than about
1/3 of a wavelength (i.e. for XX meter wavelength, about XX feet)
the Static and the Induction fields SWAMP the Radiation Field.
For a Magnetic Loop antenna, the Static field and Induction field
are Magnetic, so the Loop when closer than 1/3 of a wavelength to
most noise sources (which are ELECTRO-STATIC in origin) will not
"HEAR" any Electo-Static interference, if at all. Effectively,
the fields only become a Radio Wave at about 1/3 of a wavelength.
Rough Calculation, 80 Meters are Static to 80 feet, 40 meters are
Static to 40 feet, 20 meters are Static to 20 feet, get my drift?

Without disparaging him, how much University Physics has W8JI got?

I must disagree with you there. Let us consider a permanent magnet.
It has a magnetic field (I think you will agree), and if it is not
moving, there is NO ASSOCIATED ELECTRIC FIELD. Low Frequencies
approximate a DC permanent magnet, so there is a STRONG magnetic
field close to the (Magnetic) antenna, and only a very WEAK
electric field close by. Q.E.D.

I have a Batchelors (Honours Physics 76) and Masters (Physics 78)
so I think I can speak with some authority on the following:

All antennas have three fields, the Static field, the Induction
field, and the Radiation field. The Static field falls off as
1/(R*R*R) with distance, the Dynamic field falls off as 1/(R*R)
with distance and the Radiation field falls off as 1/(R) with
distance R. At a distance of 1 Radian (1/PI) of a Wavelength, all

I don't think anyone is arguing the point that the loop antenna works better than a whip in an RFI environment. All I am saying is that any antenna in an RFI environment does not work as well as in an RFI free environment. Just because you use a loop does not make the radio immune to RFI. I found the argument quite irritating .... and as a result I did an experiment in the early afternoon. I have several ferrite antenna equipped radios ... and I chose the most sensitive one and using earphones .... started noting the number of MW stations I could receive in different locations and under different conditions. I used 3 locations: in my house, on the deck of my house, and in the park at least 300 mtrs from the nearest electrical device. I also used the radio unassisted and with the assistance of a passive Hi-Q tuned loop approx. 1 ft square.

In the house (the location with the highest RFI environment) the unassisted radio could just barely detect 3 stations ... non listenable. With the assistance of the tuned loop I could hear 5 stations and 2 were barely listenable.

On the deck (which has less RFI than in the house) I could listen to 2 stations unassisted. With the Loop I could hear 7 or 8 stations and 3 were very listenable.

I then drove out to a park and located on park table at least 300 mtrs from the nearest electrical device. The difference was amazing between 540 khz and 800 khz I could hear stations on every 10 khz step on the dial !! I identified many stations (by call sign) up to 600 miles away. There were at least a dozen stations that were strong enough to comfortably listen to using the speaker and many more using the earphones.

I also went over to my truck which uses the infamous whip and I could only hear about 1/2 the number of stations (I also used earphones on the truck radio).

The only interference was atmospheric. The wx was quite good and any faint electrical noise due to lightning was way off to the west which was easily nulled.

It is clear to me that the only way you can get consistent MW broadcast reception in the RFI environment of a typical household is if the broadcast station is strong enough. Weak signal reception must have the antenna outside of this environment .... whether it is a loop or not. The loop picks up RFI at a signal strength that out matches the desired signals, and overpowers the mixer circuit and drives the AGC.

The loop may be "better ears" ..... but who can tell if you can't hear anything? True whether you have a degree or not hi h.

Again, I must disagree. With my Electro-Magnetic Studies in
Undergraduate Second Year Physics at the University of Victoria
in 1974, I learned that an electrically short antenna radiates
(and detects) THREE fields, the STATIC, INDUCTION and RADIATION.

The Static field decays as 1/(Distance*Distance*Distance)

The Induction field decays as 1/(Distance*Distance)

The Radiation field decays as 1/(Distance)

At a Distance of 1 Radian (1/PI or about 1/3) Wavelength, all
three fields are of equivalent strength. For 0.5 mHz this
Wavelength is 600 Meters, so the Radian distance is 600 Feet,
at 1.5 mHz this Wavelength is 200 Meters so a Radian is 200 Feet.

At distances shorter than a Radian, a Magnetic "Loop" becomes
increasingly "deaf" to Electrostatic induced noise sources.
The fact you can't "hear" weak signals, and the fact that a
bigger loop seems to "hear" better suggests to me that you
need a high gain solid-state (FET?) Pre-Amplifier before your
Receiver, to make up for the small capture area of your smaller
Magnetic Loop. This argument is ORTHOGONAL (i.e. irrelevant)
to whether the bigger Magnetic Loop is "better" at improving the
signal-to-noise RATIO (I emphasize RATIO, not absolute strength)
Tuning the loop helps prevent front end overload from strong
signals, this is one reason a tuned Hi-Q ferrite "loopstick"
antenna is used for portable AM radio receivers, rather than a
huge wire Lo-Q loop wound around the inside of the case of the
radio. A small ferrite core loop will actually be better than
a larger loop without the ferrite core, for the simple reason
that it is physically smaller and less susceptable to electric
fields. If you want a larger loop, such as used by Naval vessels
for direction finding (Goniometer) you will have to shield it by
wrapping it inside a metal tube that is cut so the tube itself
cannot form a complete loop and have its own circulating current!!!

I agree that the signal must not be swamped by interference.
Guidelines for AM radio suggest that in Rural areas the signal
strength must exceed 100 microvolts/meter, and in Urban areas
the signal strength must exceed 1000 microvolts/meter.

As for magnetic antennas not being sensitive to electric fields,
consider the reverse. Since when have you got an electric
shock from a strong Permanent Magnet? Permanent Magnet is as
close to DC and Low Frequency as I can think of, offhand...

Jim - the test for reception comparison inside your
home is not valid for your hypothesis. The inside
reception is affected by attenuation from the building
materials of the roof and walls and also the inside
power wiring that crosses the walls and roof, which
in effect forms a shorted turn loop. This can vary
quite a bit between buildings due to differences
in construction so the effect is difficult to
predict, but it is real. Also the deck location
may still be too near the house, may suffer shading
also from house wiring. I suggest you set up in
the yard but still close enuff to the house that
you reckon you are still within the RFI field.
I have noticed here where I live, carrying a SW
portable radio while walking, I can listen to to
several international broadcasters, walking inside
with the same radio, the less strong signals become
totally unusable.

>-Hue Miller

Hi Hue,

You may be right in that reception results are partially due to the actual attenuation of the signals. But I am convinced that the major impediment is the surrounding RFI.. I could for example extend my experiment to my farm. At the farm I am miles from the nearest electrical device .... unless I run the generator. Otherwise I use a small solar panel and battery. I use the same kind ... or even the same receivers ... and for the most part the results are about the same as operating in the park. My cabin has some electrical wiring, and of course a roof and walls ... and aluminum windows etc..

I would have included the farm as well in the experiment except it is a 30 mile drive. I also use a MW receiver with a small tuned loop for assistance. the house structure here is wood for the most part. the big difference is all the RFI from devices here at home and in the neighborhood. I don't think there is much in the way of shading from MW signals hi hi. there are buildings out at the park that are used for group picnics ... perhaps the next time we rent one I will do the experiment over again ... just to compare the building to the park bench. It might have an effect on the really weak stations. Before answering you I took a look at my log notes from the experiment and even surprised myself. I am located on the n.shore of lake superior. I logged CBC (Canadian Broadcast

Corporation) on 540 khz which i know is located in the small town of Watrous in central Saskatchewan no less than a 1000 miles away ... and CBC on 990 khz located in Carman in central Manitoba about 500 miles away. I also logged many stations in Minn., WI, and Illinois. I didn't log any Canadian stations to the east ... although I know there are no 50,000 watt stations until you hit Toronto. There is a 50,000 watt station there on 740 khz ... which used to be CBC but is now privately owned ... but very popular. I expect the western stations will go soon as well as just about every city and town now is covered with FM broadcast. that is the reason I can do MW DX from my location since the last MW station here (on 580 khz) closed down almost a year ago. Having a strong local station ... or any local stations de-sensitize most run in the mill MW receivers .... usually through overpowering the mixer stage. After this ... weak signals are out of the picture. In this sense even a crystal set works better than most inexpensive superhet radios.

No, there is little doubt .... the difference between hearing weak MW stations and not hearing them is the presence of RFI. In fact, I would not have had the logging success I did last afternoon if it wasn't for the broad high pressure zone overhead ... no lightning crashes and static. Even that is enough to overpower low level MW signals. In any event I am always amazed at MW and LW signal propagation. I would have been able to hear 20m stations at those distance very well during the afternoon ... but I doubt I would have heard stations on 75m. But I could hear 540 and 990 khz. Mind you they run 50,000 kw hi hi It would be nice to know how it gets here.

By the way I also run my QRP station out at the farm using my venerable Ten Tec Argonaut 509 to a 100 ft doublet about 50 ft in the trees.

Topic: 6630 Message: 6675

I am tired of this... maybe it's my age (I'll hit 61 soon.)

The E-field production of EMI within a house, which is 'radiated' by unshielded power cords and vertical & horizontal power wiring - and, to a lessor extent, conduit carried conductors, can be picked up by a loop - inside or out. It's not 'ELECTRO-STATIC', that implies a steady state charge distribution. Anyone with a modicum of understanding of sophomore physics would understand this - and recall it from Maxwell's Equations - or definition of the Poynting Vector. E-M wave propagation is via alternating Electric (E) and Magnetic (H) fields - there is nothing 'static' about it. It is capacitively coupled - and more efficiently with single-ended loops, as their CMRR is poor.

You can lessen the unbalanced capacitive coupling to a loop inside or outside a building, as our esteemed friend said, with a nearly completed conductive shield around the loop - that is then grounded (My old Drake SPR-4 had the accessory AL-4 such loop - actually, decent from LW-MW.). This is the familiar 'Faraday Shield' and can increase the capacitance across said loop, lowering it's resonant frequency. It also greatly lessens E-field capacitive coupling to the H-field designed loop. Of course, a treatise on loop antennas is included in the excellent 1950 production 'Antennas' by John D. Krause, the late (Died 7/18/2004 at 94!) great physicist/lecturer - and one of the 'Fathers' of American Radio Astronomy. Any sophomore physics text, such as Halliday & Resnick, will introduce you to Maxwell's equations, while 'Foundations of E-M Theory', by Reitz & Milford offers more detail. Neither text is a how-to manual; go to the ARRL & RSGB for good application references.

As said, it was my 'honor' to graduate in physics from Auburn U. - which I did in '75 after having started in '66. Yeah, I goofed off - got a job offer I couldn't refuse part way through (It happened back then...) - returned to AU after my release from active duty. What do you do with a BS - and even grad work - in physics? Not a big bread earner. I taught in Alabama's post secondary system - physics the first quarter. Then - pre-engineering, technologies, photography, and math, among other areas. I chiefed a few broadcast stations (4 FM & 1 AM) from 9/68-12/99, when I finally tired of midnite calls (Commercial FCC 1st Class Radiotelephone License '68.). I've been a shooting range RO and woodworker since retiring.

JRT

PS This is the internet... I could be just a 13 yr old savant with a vivid imagination, too! Remember that...

From: EDUARDO
Topic: 6678 Message: 6678

Hello friends, good night!
After 15 months of tests and trials, got the best of an antenna for loopstick MW. This antenna has the name of LoopStick Gold Edition, it has a spectacular yield, the lower antenna on the market with excellent or even say, the biggest gain. It is worth giving, this model is already in several countries other than Brazil, such as Spain, Portugal, USA, Argentina, etc..
Check out the link below:

http://www.youtube.com/user/ADCASZIZA#play/all/favorites-all/1/4lpSNiirUVk

After several experiments with other types of antennas, qeu believe this is one of the best options, because we have the smallest antenna in the market with support, portable, small, excellent, low noise, 21 cm long by 2.54 cm diameter.

Respectfully,

Eduardo L. Castaldelli

What would be better than correcting the Links.txt would be adding the links to the Links section. Can I say "links" a few more times? ;')

I created a folder for active loops and preamps in the Links section and put your new address there.

From: brian russell
Topic: 6682 Message: 6682

Hi,
Although the subject of various designs of loop antenna for reception in the 0.5 - 1.8 MHz range comes up fairly regularly I have yet to see any links to a loop antenna for FM reception, 88 - 104 MHz.
This begs the question would a loop be any advantage over the common telescopic whip ????
Your thoughts please.
72, Brian, G0NSL-QRP.

A folded dipole made from 300-ohm twinlead makes a great FM antenna.
You cut a piece of twinlead that is a half wavelength long at the middle of
the band. Short the ends, then make a cut in one conductor at the middle.
Attach the 300-ohm twinlead feedline at that point or you can connect it to
a 75-ohm balun. These work really well for the FM broadcast band as well as
part of the VHF-TV band. I made these by the dozen while in undergrad
school and sold them to dormies to raise beer money. I still have a
commercial one connected to my desk FM stereo receiver and it works just as
good as my homebrewed ones did.

The frequencies 88-108 mHz are approximately 100 mHz which
has a wavelength of 3 meters. This means that the Radiation
field does not predominate over the Static and Induction
field until a distance of one Radian, 1/PI wavelength, which
is about one meter. Thus a loop only would be of advantage
over a whip for distances shorter than approximately one meter,
i.e. about three feet.

I think you will agree with me that most noise sources are
further than three feet away, therefore I see no particular
advantage of using a loop for FM reception, 88 - 104 mHz.

My thoughts.

Hi,

As already mentioned the most common antenna used for local FM reception is a folded dipole made of TV type twin lead. I have several in the junk box and checked them out for dimensions and find they are indeed cut to a the standard 1/2 wavelength dimension (about 5 ft). It would be quite easy to design the antenna as a full size self resonant loop which would be approx. 3 ft in diameter. I can understand why the dipole is more common in that it is easier to deploy than a loop .... the loop requires more support points. A full size loop has a small gain advantage over the dipole (but certainly not the 5.5 db claimed on the skywaves site ... e.g. they claim it to be comparable to a 5 el. yagi !!). I would take information from this site with a grain of salt.

If you want this amount of gain (5.5 db) you will certainly have to form the antenna into a 3 dimensional configuration with parasitic elements. The elements can be either loops, dipoles, or a combination.

A folded dipole at first glance seems like a loop, but it is not a loop antenna. It is a dipole, which has (in its usual configuration) two wires in parallel and connected in a way that appears like a loop. But the two wires are so close together that it doesn't behave at all similar to how a loop antenna behaves. The reason for doing a folded dipole, is to get the feedpoint impedance transformation, useful since most FM radios have 300 ohm input terminals. Otherwise, it transmits and receives like a dipole of comparable size, not like a loop.

In days gone past, there were FM broadcast transmitting loop antennas, probably made that way to give them somewhat non-directional characteristics (in the horizontal plane), as opposed to a straight dipole with its figure-8 pattern. The transmitting loops I saw and used had a gap opposite from the feed end, with two small adjustable capacitor plates in the gap to tune the loop to resonance.

A VHF/UHF "shielded" (i.e., balanced) loop you might want to think about, is at http://www.arrowantennas.com/fhl.html and http://www.arrowantennas.com/loopdemo.html . I have no experience with this thing, but its advertised advantage is the sharp null which would make it good for radio direction finding, or for rejecting a point noise source at any distance.

Andy

I think that is why it is called a folded "dipole" .... hi I may be mistaken, but I don't think anyone was thinking the folded dipole was a loop.

I think someone was asking how a loop might work vs a common and somewhat traditional "folded dipole" that often comes along with your Hi-Fi FM receiver.

The full size self resonant loop would of course be 1 wavelength in circumference and in my view it would be a little big and awkward sitting on top of the Hi-Fi FM receiver. It got me thinking about a small tuned magnetic loop (usually about 1/10 the size of full size loop or about 1 ft or so in circumference or a little over 3 inches in dia. It could of course be made a little bit bigger out of heavy copper, with a nice wood or Bakelite base containing the tuning capacitor . The loop could be tweaked at each FM station frequency and rotated for best reception. I have never heard of anyone making a small tuned loop for FM reception. It might be an interesting experiment.

<<SNIP>>

The whole "folded dipole vs. loop" discussion has gone back and forth for decades, and it's more a matter of opinion rather than strict definition as to what term is used. The directional properties of the folded dipole make it a better performer than a simple whip as you get more signal (ie - pattern gain) plus you have the opportunity to null out some interference, plus it will connect directly to the 300-ohm inputs that are common with commercial FM broadcast and VHF TV receivers.

Hi,
Thanks to all who responded to my query on FM loop antennas
much appreciated.
It would seem that there is no great case for a loop, in fact spacewise there
is a downside to one compared to a folded dipole or whip.
From chimney top observations there would appear to be several types
of folded dipole antennas i.e. straight, circular and one shaped like a
letter ' S' squashed from the sides ?????
Though it may not be an FM antenna there is a common type in the UK
seen on caravans / motor cruisers, this is of a ' geodetic ' shape
about the size of a football, I have never seen one close-up so
I have no idea of the configuration of the element (s).

Hello!

It was very interesting to see and hear the effect of your
strong ferrite antenna on tropical waves!
I like to ask the price for that kind of an antenna if sent
to Spain.

Best Regards from a Finnish veteran DXer living in Spain
permanently.

Hello friends, good night!
After 15 months of tests and trials, got the best of an antenna for
loopstick MW. This antenna has the name of LoopStick Gold Edition, it has a
spectacular yield, the lower antenna on the market with excellent or even
say, the biggest gain. It is worth giving, this model is already in several
countries other than Brazil, such as Spain, Portugal, USA, Argentina, etc..
Check out the link below:

http://www.youtube. com/user/ ADCASZIZA# play/all/ favorites-
all/1/4lpSNiirUV k

After several experiments with other types of antennas, qeu believe this is
one of the best options, because we have the smallest antenna in the market
with support, portable, small, excellent, low noise, 21 cm long by 2.54 cm
diameter.

Respectfully,

Kiitos/gracias/thank you EDUARDO!

I received your message, yes, but right now I am not able to buy
that antenna, because I think, that the price is too high for my
relatively low pension...

Thanks anyway to give the details.

Best Regards from Aimo.

Greetings from Finland !

Hi Aimo and Eduardo and all in the Group !

I took a look for that Loopstick, Golden Edition.
It intrests me much because I am planning to make ferrite RX loop
for lover HF, means abt 3 to 9 MHz .
I have done some ferrite tests just to find source of local QRM
at 3,5 MHz but not yet found it. I made pararell resonance with
coil and 300 pF variable cap.
Do you have any idea how this GoldenStick is made ?
Is there Capasitance making resonance together with ferrite coil ?

best regards es 73s de rami, oh6bi

Same principle as loop antenna: a long wire (around AIR, the loopstick
has a metal, which gives shorter wire), and a variabla cap to tune. It
would be nice to compare a loopstick with a loop antenna ...

Hello Friends,
This antenna is manufactured by GE LoopStick me. Its construction consists of a coil on the ferrite stick, connected to a variable capacitor of 365pf. The signal is amplified by an amplifier of 40 dB, produced by me too. The result is amazing, wonderful, equivalent to a Long wire antenna from 70 to 100 meters. Its coil resonate in the range 2000 kHz to 9000 kHz.

6698. KA-35 reception improvement

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-07-21 05:57:54 UTC
From: Adam E.
Topic: 6698 Message: 6698

I have a plan in finding ways to improve the LW reception when I get the KA-35 controller cable fixed. I was thinking about making the
ferrite rod antenna bigger so it can pull in better than the 4.5 inch
ferrite rod that it comes with it.

Is it possible to improve the LW/MW reception with switching out the old ferrite loop stick with a 7.5 inch loopstick?

Adam E.

"Ya but ..." with the 'but' being what is inside the plastic ferrite mounting box? If it is a coil &/or capacitor, there is a matching network you will have to deal with when adding a longer stick.

I don't think you can do much better with an indoor antenna, IMHO.
Anyway, the adverb says the stock rod is 5 1/2 in. Is yours shorter???
If it is really 5 1/2 in, adding another inch on each side (for a total
of 7.5 in by replacing the original rod) won't do much for reception.
You might try temporarily adding longer pieces to each end, like 3 1/2
in rods. Use painters tape (blue) or small cardboard/plastic tubes so as
not to mark up the KA35. Appearantly there is no tuning - there is an
active amp in the box.

Again, IMHO, indoor antennas have practical/aesthetic/better half (wife)
limits. An outdoor antenna is really the way to go for better reception
if you can. Of course the ultimate hack for this would be to disassemble
the KA35 unit and mount it in a weatherproof plastic box or a large
diameter PVC pipe, like a 3 inch T-shape outside. I believe the rod
antenna is only for LW/MW though. Looks like it only needs the one
RF/power cable as well. Let us know how you get on!

Adam,
I've had good results with adapting larger ferrite rod/coil assemblies with several different base amps. My portaloop couples a ferrite loop with a Degen 31 with acceptible results, (considering its simplicity).
Also made various plug-ins for my Palomar base amp and Ramsey signal magnet. See them in ferriteantennaexperimenter group my ferroids photos section. (Portaloop and LW loop plug-in) Bottom line, whether the the base amp employs veractor tuning (Kaito/Degen, Ramsey), or variable tuning cap, (Palomar) The loop will tune. It's just a matter of dialing it in to the desired range by varing the winding numbers and diameter.
The only amplified loop I haven't modified is my Quantum QX. It's my reference to which I make comparisons. Nothing I've made quite matches up so far - at least on MW.

John

Thanks for the information there. I see that there will be major improvements using this special base loop antenna amplifier. I have some great news. I did some homebrew experiments using my knowledge
in electronics. I had trouble fixing the loop antenna element so I started to tinker around with it more. Instead of using the everyday loop antenna to capacitor in parallel connection like the framed antennas we have been building for years. I had to use the other method, I reconnected the loop antenna and variable tuning capacitor in series. Connected 1 lead from the loop antenna to the variable tuning capacitor, then connected to variable tuning capacitor to the KA-35 using the white wire NOT the red one (red one powers the optional loop antenna element. Then connected the 2nd lead loop antenna wire to the ground shielded lead. And tada the KA-35 now is using a tunable loop antenna that I built not the stock one. Which means if you're going to connect to actually any RF amp you have to use the series method.

VARIABLE CAP
\
A Loop Lead -------|(------- Amp RF Input
\

B Loop Lead ---------------- Amp RF Ground Input

Don't have time for much of a reply (Gotta Work), but Jim says most of what I wanted to say. I will point out that you will gain nothing from using Coax TV line for the large loop. Insulated wire from Home Depot, such as Bell wire, is much cheaper, and works just as well.

I would also point out that Houses and Power Lines are where noise is generated. Rather than circling the house, try keeping the antenna as far away from these structures as possible. Every foot helps. Use an isolation transformer at the juncture of the loop wires, and coax as the feed to your receiver. Don't forget the lightning arrestors. Also consider the PAR EF-SWL antenna. It is not a loop, but it is an excellent antenna for a reasonable price. And requires only one tall support and a ground rod. Trees are excellent supports if you include a pully/sash-weight support line to keep the wire from being pulled apart when the tree moves. No climbing needed.

6707. NEW LOOP

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-07-28 15:18:04 UTC
From: EDUARDO
Topic: 6707 Message: 6707

Hello for all!

This is my new construction " Antenna Loop 1,00 m. x 1,00 ms

Well built this antenna only to listen on MW. Your income is extraordinary, in rapid test could hear the station on 1610 kHz Radio Caribean Beacon in Anguilla, as well as several other broadcasters in other countries such as Argentina in the range x-band, Uruguay in 1050 kHz, recommend its construction for those who like mw.
Offer some photos on the site www.radiodx.qsl.br on page "Radioescuta"

Respectfully,

Eduardo L. Castaldelli
Grid Locator: GG66qq

6708. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-08-01 12:58:17 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6708

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

6710. Hidden stealth wire loop around UPVC gutter - Thoughts Please -

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-08-02 09:36:03 UTC
From: Colin Lowe
Topic: 6710 Message: 6710

Hi all,

I need to install an aerial that will work on 80/40m at my home QTH. I'm not looking for DX but enjoy good inter-UK contacts. One of my interests is QRP on 80m so the aerial needs to be as efficient as possible on 80m. Also if the tuner will allow the loop to be tuned on 40m & 20m, I'd be more than happy :)
The aerial needs to be hidden as much as possible.
I'm thinking of running a simple insulated wire around the clips that support the UPVC gutter of my home. The rain water gutter is 5.2m above ground level and if I install a full loop around the gutter it will total 31.4m (2 sides 8.7m and 2 sides 7m). I intend to feed the loop and tune it with an SG-237 auto-tuner from SGC mounted at the loop.
Now for the questions....
Q1. What gauge wire should I use:
Q2. Would it be worth making some loading coils so that the electrical length of the loop is about 40m and if so where should they be placed in the loop.

Any other thought or advice gratefully received.

Hi Colin

The SGC-237 should have no difficulty matching the 31m (102 ft approx) loop. The gauge will not be of consequence except as to its visibility. If the gutter is white ... then use white insulated wire and if black use black hi hi. #14 gauge and flexible would be ideal. I have some black flexible fwire that would be ideal ... It is called 'flexi-something or other'. Loading coils will be counter productive. SGC used to market a similar 'stealth' antenna that consisted of 80ft (25m approx) of insulated flexible wire which would load well 160-10m using their antenna coupler.

The antenna will load well ... however the radiation pattern will be mostly vertical on the lower frequencies ... and a bit better on the higher frequencies. However you should have no difficulty making contacts on all bands and your transceiver will be perfectly happy.

Jim, VE3CI

Resonance on 80 and working other bands harmonically related is do-able. Can you put up a loop of (ANY GUAGE) wire around the plastic gutter and extend it to 283 Feet in the garden? If that is just at fence-top height you will work 80 - 10 metres no sweat ! The results will amaze you. Use twin feeder of 300 ohm slotted ribbon to keep the noise minimal. Any feeder length will work as it it is theoretically non-radiating when you feed a balanced antenna, and the impedance will be "medium" throughout the hf spectrum.
If not, just use the largest loop that will fit into your plot and trust your SG-237 to do it's work.

If you introduce loading coils, it complicates life and gives inductive reactance which will only be ideal on one band and certainly not all. Forty metre resonance will beachieved if you cut your loop at 141Ft 6ins. This would work on 40 - 10 very well but 80 would be poor. If you have a good earth, then strap the feeders for the 80M band but expect the noise to be higher. Mike G4HOL.

Hi Colin

A further comment. You mentioned putting the tuner out at the feed point of the loop. With no doubt that will be the most effective way to feed the loop on all bands with no problems and use a coax feed line. If you place the tuner at the feed point then you can use just about anything as the antenna ... introducing a balanced feed line between the antenna and the xcvr will complicate the situation. Since you are going to use the loop on all bands resonance is not an issue. There are certain unique situations where you may use a lumped inductance with a loop. However the purpose is not to obtain resonance but to introduce a phase shift which in turn introduces some directivity in the radiation pattern. It is used in a mono-band situation where the loop is made a half-wavelength and oriented in a vertical position. The inductors are placed in vertical portions of the loop. Some of the early antenna handbooks discuss this antenna arrangement. In your case adding lumped inductance will serve no purpose.

Jim, VE3CI

6714. Re: Hidden stealth wire loop around UPVC gutter - Thoughts Please -

Topic: 6710 Message: 6714

Many thanks Jim and Mike for you reply's.

Weather permitting I will install the loop this weekend and report back on it's performance. I plan to run a length of RG213 from the shack into the attic and then out to the SGC tuner mounted under the eaves. Then I will run a 1mm insulated wire around the outside of the plastic gutter and back to the tuner in a loop. For the time being I will keep it just around the house and not extend it to run down the garden as I want to keep it hidden as much as possible.

Thanks again and I will report back next week once I have tested it's performance.

6715. New Yahoo group formed to discuss simple antenna building - all welcome

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-08-10 13:36:42 UTC
From: Stan
Topic: 6715 Message: 6715

This is to let the amateur radio and SWL community know about a new Yahoo group for the discussion on simple antenna construction.
http://groups.yahoo.com/group/Radio_Antenna/

A discussion group restricted to the technical aspects, methods and techniques for developing and building amateur and short wave listener radio antenna

Members of the list are encouraged to ask questions and post answers, links, photos and files with the discussion directed to their experience, needs and solutions.

Portable and QRP applications are of special interest to the group.

Please feel free to post your EZNEC files and results. I am in the process of learning how to use this powerful tool and expect others interested in building antenna would be also.

Stan AK0B

6716. New Loop

Yahoo group: loopantennas (2008 — 2012)

From: dean_0_way
Topic: 162 Message: 6716

After messing around with a mini Bog wire antenna for a few day's i started to think of my next project;

I have a crawl space in the upper part of the house that would be a nice place for a Bigger Loop,so in preperation for that ,today i built a 3 foot loop with 4 inch wood ,added 8 turns of 18 ga. insulated wire ,and an old 2 stage tuning cap.

I went outside with it for the first test,in the middle of the afternoon it will clearly bring in stations of the 5000w range from 300-400 miles away,also had one from 200 miles away that is a 500w.

But as you might suspect my old nemesis is back ,besides the home freg. I now have several harmonics above and below 1350 ,so what i'm wondering is if there is a way to block that 1350khz signal,and if that's possible will it also kill the harmonics?

Iv'e been looking around for a fix but have'nt come up with a great fix so far .

Tonight I will test it again after my local powers down but i'm sure the results will be about the same,and i want to see how far i can push this loop. :)

If i can get some magic bullet for this problem i'm going to build a second loop and try to phase them both in the crawl space,as soon as i figure a way to adjust the tuning cap from 10 feet away ? lol :\

Any help appreciated Thanks

Dean_0

Hi,

Not sure what you mean about harmonics and how they relate to 1350 khz. .... e.g. 'your nemesis'. Is it a strong station on 1350 that appears on your receiver at other points on the dial ??? . Either the station is overloading your receiver front end and/or the image is coming through. What you describe sounds like a receiver problem. 1350 khz can't be a harmonic since the fundamental would have to be 675 and stations are assigned at 10khz intervals ... e.g. either 670 khz or 680 khz. If the station is on 1350 then the harmonic would be 2700 khz ... way out of the MW broadcast band.

Describe what you are hearing. Forgive me if you have already done so.

Jim

The station is at 1350 khz and a block and a half from my house ,the harmonics i refered to was i get that station on 1280 and several places above 1350,so i think your right about overload,as you might have guessed i'm putting big antennas on smaller radio's to get distant DX ,just to compare i have a 2100 kaito with a 16 inch tuned loop on it and sometimes it does the same thing although not as bad,

Beside this station my nearset other AM station is 70 miles away so you can see i have a pretty tuff time getting enough gain to recieve far away, with this flame thrower in my back yard, he heh.

But i thought with a little black magic i might figure it out ?
Besides i don't have enything else interesting to do :\

thanks ,

Sorry, I don't see why a big loop is required for RECEIVING.
I have a six transistor AM-only Radio (500-2000 KiloCycles/sec)
that picks up stations from all over North America when I use
it here in my ground floor suite in this multi-story wood frame
apartment building. The loop antenna is a small multi-turn
loop wound on a Ferrite (Ferrite is Magnetic) 1/2 inch diameter
rod. Please note the difference between CAPTURE AREA
(i.e. how much signal an antenna "brings in") as opposed to
the SIGNAL/NOISE ratio. A deficit in CAPTURE AREA can usually
be made up with a high gain low noise solid-state preamplifier.
In my case of my portable "PLAY-MATE" six transistor AM-only
radio, the loop is HIGH-Q (very low loss) and is tuned in
tandem with the oscillator by the two-gang capacitor in the
radio. (One gang for Loop, one gang for Heterodyne Oscillator)

Receiving loops do NOT have to be efficient. Transmitting loops
do, so they are usually bigger. For info on Transmitting loops

What kind of super radio is that "Playmate"?
The only one I found that was close with the name playmate.

http://www.richardsradios.co.uk/playmate.html

>"500-2000 KiloCycles/sec" That is an Odd range I have never heard in AM radios. Is that a European thing? How old is this thing?

Please tell us more, where do you live and what stations have you logged. I am impressed if its all over North America. I'm going to get one of those playmates. Also could you give the design specs for that super loop you have. I'd like to replicate it.

I have a tiny pocked Realistic AM/FM radio (late 1990's) with digital tune. With my Terk AM Advantage 9" loop I can tune in some impressive MW DX stations. The internal loop stick is 2.5" long (may be even closer to 2").

What do you have against large loop antennas? The larger loop also serves in other aspects, such as LF reception. Many people DX with crystal radios or one tube radios. If the conditions are right you can do amazing things with basic receivers and antennas.

Cheers George

PS that is a serious home page you have.

Hi Dean_O

I understand your problem and empathize with you. At my location ... I have no local MW broadcast stations within a couple of hundred miles!! MW DXing is a pleasure. back to your problem. If you want to work DX on MW with a strong local station the ideal receiving combination would be as follows:

1. A receiver WITHOUT a built-in ferrite loop antenna .... or at least disconnects the ferrite loop antenna when you plug in an external antenna.
2. Construct or purchase a HI-Q band pass filter (pre-selector) which can be placed between your external antenna and your receiver antenna input.
3. Construct your external loop (not too big ... and located where you can adjust both orientation and coupling to the receiver)
4. You could make 2 similar loops .... The first loop that tunes the desired station must be oriented for maximum null on the 1350 station. Jiggle orientation and tuning for best reception of DX station. The second loop can then be oriented in relation to the first loop and tuned to the 1350 station. Jiggle orientation and tuning to

minimize 1350 reception. In other words, the second loop is simply brought into the vicinity of the first loop and will 'suck out 1350 signals. This is an old trick used by crystal set radio aficionados.

When you 'jiggle' the tuning in the second loop you are adjusting the phase of the 1350 signal such that one loop field cancels the other loop field. There is commercial gear available that will accomplish this ... and they are advertised as noise cancelling devices. MFJ makes such a device.

Between nulling and phasing your 2 small loops the DX station is maximized and the interfering station is maximized. Ideally the first loop would be coupled to the radio via the preselector. However if your radio has a ferrite loop then it will be inductively coupled to the loops and will have to 'jiggled' as well.

Jim

Dean-o,
I think a simple filter can be made with a coil and variable cap in series with the antenna (that is, between the antenna and radio, coil and cap in series with each other) and tuning the variable to null out the offending station. I read this somewhere, but my computer is in the shop and all my links, etc. are on it. Capacitor should be standard 365Pf variable, coil can be anything that will resonate on the BC band, a small ferrite from an old radio would probably work. However, if it's overloading the front end of your radio and getting into the IF stage, then this probably won't work!
Then I would try to shield the whole radio; if it's small enough, you could put it in a cookie tin or similar, if it's big, you could foil the inside, just make sure the foil doesn't short out to anything, and make sure it's grounded.

Some things to try, anyway. Good luck and keep us informed,

Pappy Hiram

The first person to mentioned band pass filters, rightly so, gold star for them. You can build a band-pass or band-stop/notch, low, high for that freq.

http://en.wikipedia.org/wiki/Band-pass_filter

Lots of info on the web. There are plans to make a filter box with selectable freq. This goes on the front end.

Try making some filters, they are easy to make.
http://www.arrl.org/tis/info/rf-filter.html
http://focus.ti.com/lit/an/sloa093/sloa093.pdf

There could be some local RFI on that freq. Have you tried to hunt it down, Direction find or is it omnipresent? Have you tried different radios?

I have two strong MW stations near my home at 850KHz 3 miles (10KW Day 5 KW Night) ... AND ... 680 KHz 6.6 mile due East (50KW Clear channel, Omni day, N-S Night). Thankfully at night they go directional (I'm to the side of pattern) or drop power in half. Surprisingly they don't cause much problem; except I forget DX'ing any stations on those exact two freq, especially to the West or S-West and N-West, which is too bad. A loop is great, but if I point it West, it is pointing East as well. When I point my Loop more or less N-S the two strong stations to the East almost disappeared. YEA for LOOPS!

May be I can get a omni directional antenna, but my loops have classic bi-directional semi omni patterns. If I point them West they are pointing right at these stations East. There are stations on these two freq to the West in TX, MO, IA, GA, NM, MT, CA, WA I just can't get. When the stations are North or South no problem with the loop and good radio.

These stations don't cause to much problems for me with a loop antenna an a digital PPL Dual conversion radio with a dozen internal RF microprocessor controlled filters and selectable band width, I don't have problems.

However with my old 1940's and 50's tube radios (just Zenith AM/FM, no super SW boat-anchors), there are intermodulation issues and may be image rejection issues. Superhet radios have good qualities but some draw backs. You may know all about superheterodyne radio design. I am no expert but Image response or image response rejection ratio (IMRR) can cause problems. If you have an issue with 1350Khz the problem may be 455Khz lower, say at 890Khz or 900Khz. Is this a problem on all your radios? What kind of radios do you have? Do you have a strong station nearby (radio-locator.com).

Also Graveyard channels, where lots of low powered stations operate, typically 1220-1500khz, 1230, 1240, 1340, 1400, 1450, and 1490khz, makes a mess at night anyway. 1350Khz is in that ball park.

Cheers

Like Jim suggests, I use a 2ft multi-turn loop and a CCrane Twin-Ferrite. The T-F direct connects to the radio, the head of the T-F is placed very close to the loop. I play one pickup pattern atgainst the other and can null two stations which are physically only 30 degrees apart. That's impressive. Yes, it takes some "jiggling" but not only do I get super-tight nulls, the gain from the two antennas is literally 1+1 (doubling gain of either single antenna) and since both loops are tuned circuits, I get no overloading or image problems.

-Mark

Ok great maybe when you get your machine back if you have a link you can post it for me?

Thanks for all the info guy's i found many of the same links that were posted ,the only problem is that i am schematically challenged , or was that schematic A-D-D? ;0

This is to let the amateur radio and SWL community know about a new Yahoo group for the discussion on simple antenna construction.
http://groups.yahoo.com/group/Radio_Antenna/

A discussion group restricted to the technical aspects, methods and techniques for developing and building amateur and short wave listener radio antenna

Members of the list are encouraged to ask questions and post answers, links, photos and files with the discussion directed to their experience, needs and solutions.

Portable and QRP applications are of special interest to the group.

Please feel free to post your EZNEC files and results. I am in the process of learning how to use this powerful tool and expect others interested in building antenna would be also.

Yes. I subscribed via the web (go to the URL specified and click on Join).
Of course you need a Yahoo ID to join that way.

If you prefer the email method to join, if your emails sent to
"Radio_Antenna-subscribe (at) yahoogroups.com" bounce back to you, then you
probably have a typo in that address. The address of that form is
universal to all Yahoogroups and ought to work.

Andy

From: jr_dakota
Topic: 162 Message: 6734

That's pretty much how I built mine, I bought a 3 dollar radio at a dollar store and took out the loopstick and tuning cap since it's already set up to tune the AM band and placed them in series between the antenna feedpoint and ground

I would recommend putting it in a shielded box and place it right at the feedpoint of the antenna ... It'll be outdoors but you only need to tune it once so that's not a big deal

The notch will be kinda broad so you'll lose a station or two just below and just above the target station .... If you need a narrower notch then you need a higher Q inductor/coil like an aircore wound on a piece of 1 1/2" PVC

But for most people the ferrite loopstick will do just fine

JR

>
> Dean-o,
> I think a simple filter can be made with a coil and variable cap in series with the antenna (that is, between the antenna and radio, coil and cap in series with each other) and tuning the variable to null out the offending station. I read this somewhere, but my computer is in the shop and all my links, etc. are on it. Capacitor should be standard 365Pf variable, coil can be anything that will resonate on the BC band, a small ferrite from an old radio would probably work. However, if it's overloading the front end of your radio and getting into the IF stage, then this probably won't work!
> Then I would try to shield the whole radio; if it's small enough, you could put it in a cookie tin or similar, if it's big, you could foil the inside, just make sure the foil doesn't short out to anything, and make sure it's grounded.

6737. Advice on Direction Finding Loop for UHF

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-08-19 14:28:05 UTC
From: Frits PE2G
Topic: 6737 Message: 6737

Hello all,

I'm new on the list.

I'm contemplating to build a (small) loop antenna for Direction Finding on UHF, mainly because of its simplicity and handy size. The freqs used are in the 401-406 MHz band (weather sondes in Europe) with a center freq of 403 MHz. The loop should provide a good null on a signal from a radiosonde that is already on the ground and at close range.

Would you recommend a full wave loop or one smaller than that?

Any other suggestions are appreciated!

Many thanks and 73,

Frits PE2G
JO32HI

Either a Moxon Rectangle antenna, or a Yagi would work better as you would have a null or peek in one direction.

This is not meant to be an endorsement (and I have no experience with this model) ... but Arrow Antennas sells a small loop that includes UHF:

http://www.arrowantennas.com/fhl.html
http://www.arrowantennas.com/loopdemo.html

They appear to be "shielded" loops (though the mention of a "Faraday shield" is incorrect, it is not a true Faraday shield, if it were the antenna would not receive at all), and they probably contain a balun in the base to maintain the loop's balance (essential for good DF nulls). Given the frequency ranges (no lower limit), and the diagram showing the null perpendicular to the plane of the loop, these would be small loops.

Andy

6740. magnetic loops for xmit and receive

hi brian,
i'm also interested in magnetic loops, for AM broadcast band reception and QRP xmit/receive.

my first AM antenna netted me 146 stations with best DX about 1000 miles. using 8 turns of 22 ga wire and a 1100 pf var cap. I plan on upgrading it with litz wire.

i'm getting ready to build a multi-turn loop for 40/30/20 meters. using 8 ga wire (0.125" or about 3 mm). it will be 4 turns.

what have you done so far with loops ?

For reception, the bulk and induced resistive losses are of little consequence if the loop is parallel-tuned, such as we would commonly see for ferrite-loaded (aka ferrite rod) loop antennas:

http://www.home.earthlink.net/~christrask/Paper006.html

and the same is roughly applicable to other forms of loop antennas, especially when using multiple turns. However, when transmitting these resistive losses have a heavy impact on the antenna efficiency, especially since the antenna must be series-resonant in order for current to pass through it to generate a radiating EM field.

To get the best overall efficiency for transmitting, the loop should have as few turns as possible, and the conductor should be of fairly large diameter, 1/2" being a practical lower limit:

http://www.home.earthlink.net/~christrask/Paper012.html

At low frequencies, multiple turns become necessary so as to avoid a large loop diameter, and in such cases the turns should be at least 5 conductor diameters apart so as to avoid excessive intra-winding capacitance.

Thanks for that, Chris.
I used up 500 feet of 14 ga. stranded wire in an attempt to make a super broomstick. It turned out to be a lousy reception antenna.

Has anyone experimented with a 'ball antenna'. This could be formed of a very stiff wire and the windings would cross at the top and bottom. In some places the wire would be much further apart and obviously they would be overlapping at the poles. Any idea on what properties it might have before I invent another way waste wire?

Thanks, Stanley and Andy, for your suggestions. The small loop from Arrow Antennas looks most promising to me. I usually know in which general direction I have to search, the problem is the final stage of the search, when the radiosonde is somewhere on the terrain at a range of <100 meters. When the transmitter is at close range, but still invisible in the vegetation, I need a sharp null.

From: wa8lcz
Topic: 6740 Message: 6744

hi chris,

i sent a response to this email but it got lost in yahoo-land. so the short answer is:
1. the litz wire is for the AM broadcast receive loop, and it will be coupled to my receiver. litz works extremely well in crystal radio coils and should work well here.

2. the 40/30/20m transmit loop will be 8 ga wire, because thats what i have on hand and the loop needs to be portable, lightweight and i'm not sure how well it will work, so i dont want to put too much money into it. i ran the numbers in a loop calculator and realize how much more efficient 1 inch copper tube would be and how much less bandwidth i would have.
dia mhz bandwidth efficiency pwr in/out
.125" 7 35 khz 45% 10/4.5 watts
1.0" 7 26 khz 88% 10/8.8 watts
all i have to do is increase power to 10 or even 20 watts and i'll have a respectable signal. even at 50w the rf voltage won't be higher than 2.3 kv. the var cap i'm using is rated at 4.5 kv and probably good to twice that amount.

but life and ham radio are a compromise.

alex py1ahd www.alexloop.com is using a 3 turn loop on 80/40m and its working on 40m fairly well, and his turn spacing doesnt look much more than 1 or 2 turn diameters. once again, compromise for a portable lightweight loop. by the way, check out his website, its loaded with interesting ways to build loop antennas. for adjusting them, he uses dc motors, RC servo motors, two surringes hooked together with tubing and filled with water to adjust a var cap, homebrew var cap made from pc board material and other cool tricks.

There are some interseting things there but i cant figure why he is going to the trouble of having the tuning cap at the top of the loop ,seems like it would be much simpler to have it at the bottom ?
Maybe i'm missing somthing?

if you feed the loop at the bottom, the capacitor goes on the opposite side. Makes for some interesting contraptions.

I designed out the need for placing the variable capacitor at the top:

http://www.home.earthlink.net/~christrask/Paper012.html

The far end of the loop has the highest voltage gradient, and the high
voltage vacuum variables needs to accomdate that tend to be very expensve,
let alone leading to mechanical difficulties in mounting it out on the far
end and then needing a non-conducting shaft going that distance to adjust
it.

The base end of the loop has the lowest voltage gradient, and you can
use alomost any dual air variable for tuning. Thre is some difficulty in
accomodating variables with a common shaft and a grounded frame, but I
eliminated that problem as well. If I wanted to go to the effort, I could
use a single variable, but that gets into problems of insulating the
variable from ground.

hi dean-o

some loop construction articles say the loop works better with the feed (loop or delta or gamma match) closest to ground. when the var cap is high, it makes the loop top heavy, but it seems to be the way most loops are made. alex adds an extenstion shaft to his caps to keep the tuning knob low, to make adjustments easier. it would be interesting to try it both ways. cap high or cap low.

Less than 1dB for the entire network. The first one, the 1:4 BalBal built on the powdered iron toroid, was an important factor in the losses, and the transformer that couples the variable capacitor was second, which is why it also was built on a powdered iron toroid. Ferrite toroids are very lossy when used in low impedance circuitry.

That last line is news to me. Can you help me understand
why it is true?

I am pretty sure I can beat any powdered iron core
transformer you make with one made with the best ferrite
material and core size and shape for the job.

What am I missing?

Not entirely certain of the mechanism surrounding the higher losses,
except that it has to do with the induced eddy current and bulk losses of
the material. I found out the hard way by experimentation. I made the
first of those two transformers using the familiar Fair Rite 43 material,
then tried 61 (which is far less lossy), then tried powdered iron.

In 50-ohm circuitry, the difference in losses is almost unnoticable.
But in the 3 to 4 ohm range of the first transformer, there was a great deal
of difference. The difference was not as noticable for the second
transformer, but it was still a factor in deciding which material to use.
For the third transfomer, which is a 12.5 ohm to 50 ohm BalUn, there was
little difference.

I found the same to be true for the varactor-tuned receiving loops, and
that's why those have the same mix of materials for the transformers.

Thanks for the explanation.

Were those different versions all made with essentially the
same size and shape of core, and with the same number of
turns? If so, I don't think you made best use of material
with at least two of them.

I guess I should review the design you have provided and
suggest how I would replace those transformers with ferrite
cored versions that I think would work better, if I can.

They were entirely different. The ones for the transmitting loop were
about 1" in diameter, using parallel wires. The ones for the receiving

loops were T44-6 cores using twisted wire, and in those only the first transformer was a toroid, the others being balun cores, plus I used a different impedance ratio. Still, the results for the 4:1 balun were essentially the same.

It makes me wonder about the losses in the input matching transformers for HF bipolar power amplifiers, as that is very low impedance circuitry.

Dear John

know the feeling

however those are pretty good prices

just sending Jerry a letter re "optimal fractal counterpoise" btw as regular low height antenna (something I might try for 80 and 160 m) requires so many radials ~ 100, just thought I would ask Dr Sevick if he has considered the use of other geometry to achieve a good counterpoise or reasonable counterpoise.

back to the discussion with Chris

this question of inherent losses has become important to me as I might have to make a 100 watt balun some for antenna for my HF TS-180S transceiver

I just ordered two 240FT61 thinking this might be ok

I am thinking about 80m here so what you guys come up with might affect my consideration here

I do not think I have any iron powder toroids in my limited inventory

being retired I also have to consider carefully ordering ham stuff, although my wife is very good about things

not drunk, not on the golf course and not chasing other women is one of her rationalizations to keep me happy in my hobby

best wishes to you and Chris

Chris,

I reread the details of the transformer designs for the
transmitting loop in:
http://www.home.earthlink.net/~christrask/Transmitting%20Loop%20Antenna.pdf

I need to clear up some details of your design.

You write, "Transformers T1 and T2 are both constructed
with a pair of six-turn windings of parallel #22 AWG wire on
Micrometals T106-6 toroidal cores."

By your description, it sounds like windings are made of
paralleled strands, but you mention only two pairs (4
strands total, for the 4 winding transformer in the
schematic, so I am not sure I am understanding the
construction. In the photo, It looks like only 2 or 4
strands side by side per turn, definitely not eight per turn.

I will assume 4 strands total (a pair of pairs of strands),
wound 6 turns. But the transformer schematic shows 4
windings, so I can only assume that each of the 4
schematically represented windings is only 1 strand of #22
(0.025" diameter.

In T1 the loop current passes through with 2 windings, in
parallel. That concentrates about 2.5 times as much
resistive loss per length of conductor in the transformer as
in the loop ((1/2 the current) squared through 1/10th the
circumference or 10 times the resistance per length),
assuming AC resistance is proportional to conductor
circumference and neglecting any proximity effects (which
may get worse for the windings on higher permeability cores).

T2 looks to have the same resistive loss per length of winding as T1 (about 2.5 times that of the loop conductor), because half the loop current passes through 1 strand of #22 in each winding, so same current per strand as in T1.

T3 has the same loss per length on its 12 turn winding, because it passes the same series resonant current as the windings of T2 (half the loop current) through 1 strand of #22.

The 24 turn winding of T3, (with (1/4 of the loop current) squared times 10 times the loop resistance per length) has the about the 5/8 the loss per length as the loop and about 1/4 that of the windings on T1, T2 and the 12 turn winding of T3.

All this is based on a conductor circumference that assumes the skin depth is significantly less than the radius of the smallest conductor. I think this is the case, here, at 40 meters (7 MHz), with a skin depth less than 0.001" and the radius of #22 at about 0.0125" or at least 10 skin depths.

Can you confirm or correct this part of my understanding of your design, so far, especially the strands per winding of T1 and T2? Thank you.

The windings on T1 and T2 are arranged in parallel pairs, six turns on
either side of the core. They were done that way so as to make the
interconnections easier.

Duh! I didn't notice that 12 turns were shown, not 6. So is each of the 4 schematically shown windings only 1 strand of #22 as I assumed?

Do you still have this assembly handy for testing? If so, would you be interested in testing any transformers in it that I construct to compare with those you made? Or has that train left the station?

I don't have much in the way of test equipment to test a complete unit on my own.

Yes, just one, and they're arranged in pairs similar to how you would assemble a 1:4 Guanella BalBal on a binocular core. As you noted earlier, the wire losses enter into the picture at these impedance levels, so the toroid material and number of turns became a real design issue. You can also use -6, -10, or -17 material for higher frequencies and -1, -8, or -3 for lower. But, the bulk of the losses earlier were due entirely to using mix 43 and 61 ferrite materials.

Because of the losses and nonlinearities of ferrites, I devised a method for improving the performance of lossless feedback (aka Norton) amplifiers by keeping the wires arranged such that they do not couplke to the transformer core. This is a bit tricky, but the results are worthwhile. I'm working on an article for High Frequency Electronics about it.

The assembly is intact, but I have a limited amount of cores (toroids and binocular) in the larger sizes. I was going to put up a minimal stock of a wide range of sizes and materials, but the economy (or rather lack thereof) caught up with me.

I am developing a hunch that the higher permeability of the ferrite cores allows a lot more flux per amp to encircle each conductor that is against the core, compared to the flux that goes all the way around the core. In effect, this raises the transmission line impedance of a pair of paralleled wires (more inductance per length without changing much the capacitance per length) which would make the transmission line transformer a poorer match to low impedance loads, effectively reducing the part of the energy that was carried by the transmission line versus that carried by the transformer. Having the high permeability material against one side of the conductor may also crowd the current away from the core (a proximity effect), increasing the effective AC resistance of the wire.

If the wires were spaced just their own diameter or so from the core, this effect would be significantly reduced and would be a simple test of this hunch is it increased the efficiency of the ferrite core versions. And if that worked, other means could also be used to reduce the effect, like interleaving winding strands that share the total winding current and lower the transmission line impedance.

I very much look forward to seeing that.

I make all my binocular cores out of a pair of long form ferrite beads. A pair of these are often cheaper that a single binocular core and there are more choices of sizes and materials. This is what I am thinking of as a replacement for T1 and T2, with only 1 turn (made of two or more strands in parallel) passing through each of the tubular cores.

Very simple to wind, compared to larger toroid cores. Especially good for low impedance transformers. Separate windings can exit either end of the core pair, just as with the binocular cores, so some flexibility for the connections. A typical open circuit 1 turn winding impedance is on the order of 100 ohms at 5MHz. No more turns are needed to match 3 ohms to 6 ohms. A plastic sleeve slid into each core hole to keep the wire from contact with the core reduces the hypothetical proximity effect I mentioned at the top.

Hi,
I have found by orientating the antenna in the horizontal mode
that I can hear UK stations that there is no sign of in the vertical mode.
Living on the coast I have always found it difficult in respect of ' nulls '
as there is nothing to the West other than Ireland.
In general it ' hears ' better all round if less directional.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

WIRE "Flex-Weave" Antenna Wire
"Flex-Weave" is a hybrid aerial wire that consists of 168 strands of woven #36 solid copper wires that provide high strength and extreme flexibility. The most popular version of "Flex-Weave" is the 'equivalent' of #14 AWG wire size. It can be 'used' for unsupported spans up to 200 ft (100-150 ft in areas with high ice and wind loading).
http://www.radio-ware.com/products/fw.htm

WIRE "QuietFlex" Antenna Wire by Antennas & More: Insulated, Strong, Flexible and Durable
"QuietFlex" Antenna Wire by Antennas & More: "QuietFlex" #14 AWG Wire has more than 41 Strands tightly twisted together under its Flexible Insulation making it both Strong, Flexible and Durable.

6773. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-09-01 13:41:54 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6773

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Hi all,

I' m new to this Group that I joined having a strong interest in building Loop Antennas. The QRM is one of the biggest problems of my QTH, so I think I will use a Loop for receiving and a Vertical for transmitting.... But I have to read a lot, before that.

Thank you in advance for your suggestions and

6787. FM only Home Theatre System

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-09-10 16:02:32 UTC
From: dmpienta
Topic: 6787 Message: 6787

Not sure this is the right group to help me out....

I bought my mom and dad a new 5-disc all in one home theatre system. But, it only has FM receiver/channels. No AM. I hooked it up to their whole house surround speaker system. They like their morning AM station. How do I get the broadcast of that AM station through the speaker system and /or the new surround system? I need a simple solution as I am not an expert in this field.

What to buy and how to hook it up.

Thanks,

Dana

¿Ne parlez vous en français?

Chris

My high school French was weak but I learned to say, "Je parle Francais un peu" and I can belt out the French National Anthem somewhat poorly. French speaking groups in Quebec (and other languages throughout the world) do appreciate even a few phrases we "American version of English" speaking folks have. But then there are the Cajuns that wreck both English and French in such a cute way that generates Boudreaux and Thibadeaux stories. Thanks for the translation page.

(Yeah, not really the right group because it isn't antenna related.)

Long ago, it used to be possible to buy an AM/FM tuner, but those days are long gone. You can still get separate AM tuners, used, but it's not easy to find them.

You can purchase a separate AM radio, or AM/FM receiver, and hook it in. There are all kinds of possibilities, not all cheap, and some with "some assembly required."

For example, even a portable AM radio can be hooked in, by taking its speaker or headphone output and running it into any available line-in jack on the home theater system, probably with a Y-adapter to send it to both channels.. It works, even if it's not ideal and may or may not sound that good.

Unless you swap it for a new all-on-one system that includes AM, you would end up with separate components which might be more than your folks want to deal with.

By the way, most AM/FM stereo systems have incredibly crappy AM receivers. They can be improved by adding a real longwire antenna instead of using the built-in one, but even then they tend to be very muffled.

If I remember correctly, the GE Superadio(?) is supposed to have a good AM section, but from what I read the Superadio 3 is not nearly as good as earlier models were, so it may not be such a good choice anymore.

Andy

Go over to e-bay and search for AM/FM tuners, such as Sony and Bogen.
You'll find them with RCA L/R outputs to feed to the stereo system. Some come
with small loop antennas for the AM reception.

> I built a passive 40/80m loop antenna with 35mm sq. copper cable, 10mm diameter copper tube is ideal. Diameter is 1m and it receives well enough to use with my softrock SDR receiver. The tuning is critical and a variable capacitor is required. I used a 34-1325 pF variable capacitor and I can tune 40m to 80m with it. The variable capacitor joins the two ends of the loop together and the coax cable screen connects to one side of the variable capacitor. The centre of the coax is connected to an insulated 1mm sq. cross sectional area cable. The cable is wrapped around the loop about 10 turns and clipped onto the loop with a large crocdile clip about 3/4 the way round. The winding starts at the point you connected the coax screen to the loop. For receive the croc clip position doesn't matter. For transmitting the SWR can be adjusted by moving the position of the crocodile clip. By tuning the capacitor different frequencies can be selected. This is a high Q antenna and great for nulling out noise.

6797. 40/80m loop Receive/Transmit G3LHZ Loop Aerial

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-09-17 15:35:37 UTC
From: Steve
Topic: 6797 Message: 6797

I built a passive 40/80m loop antenna with 35mm sq. copper cable, 10mm diameter copper tube is ideal. Diameter of loop is 1m and it receives well enough to use with my softrock SDR receiver. The tuning is critical and a variable capacitor is required. I used a 34-1325 pF variable capacitor and I can tune 40m to 80m with it. The variable capacitor joins the two ends of the loop together and the coax cable screen connects to one side of the variable capacitor. The centre of the coax is connected to an insulated 1mm sq. cross sectional area cable. The cable is wrapped around the loop about 10 turns and clipped onto the loop with a large crocdile clip about 3/4 the way round. The winding starts at the point you connected the coax screen to the loop. For
receive the croc clip position doesn't matter. For transmitting the SWR can be adjusted by moving the position of the crocodile clip. By tuning the capacitor different frequencies can be selected. This is a high Q antenna and great for nulling out noise. Make sure you use a wide air spaced variable capacitor if transmitting. Photos are posted here

Dear Steve

very very nice and slick
how many watts do you run thru this
I know an old guy in Guelph here who needs something like this for his appartment building
He is on the ground floor and has a little balcony

this looks perfect and he runs a barefoot Kenwood machine 100 watts I believe

best wishes and thanks for posting
Paul in Guelph ON Canada

I haven't transmitted on it yet as the capacitors I use are only low voltage rated. With the correct capacitor 100W should be possible.

I have now built a rectangular loop that covers 180m, 80m and 40m. I converted an old aluminium FM yagi (commercial radio receive) antenna that I had in storage. I will publish the results and pictures in due course.

6801. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-01 13:39:43 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6801

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

6803. operating from apartments

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-07 20:43:57 UTC
From: Zephyr
Topic: 6803 Message: 6803

Greetings fellow hams,

Thanks for having me. I want to pick your brains already :)

1. If you could choose a city apartment rental floor from which to work DX (and local) on all HF ham bands to include 160m (and VHF & UHF), which floor would you choose? This includes operating from indoors, and from a balcony or fire escape. Let's assume for simplicity's sake that any floor you choose has a clear line of sight to the horizon in at least one cardinal direction. (The apartment building isn't surrounded on all sides by taller buildings.)

2. Which floor would be the lowest floor you would consider?

3. Is there such a thing as a floor that's too high for good radiowave propagation? (Let's be reasonable. There is no Tower of Babel Apartment Complex in this city ;)

4. What if you could choose any rooftop from which to operate from time to time? How high would your rooftop be? How many stories?

5. What kind(s) of antennas not permanently installed would you use?

Thanks in advance.

73,
Frank

Out of curiosity, what is the construction of the apartment?
Wood-frame? Reinforced Concrete? Masonry?

Indoor antennas may work well from wood-frame apartments yet
be useless inside reinforced concrete apartments.

Hi,

15 years ago I worked from 9th floor with a magnetic antenna in the balcony, on 7 Mhz band with 80 wtts. It was OK for local contacts and also inside Europe. In same location I put a monoband vertical for 28Mhz on the top of the building (30mtrs high) and it was great !!!
If I could choose again, I try to put a delta loop on the top of building, calculated for 40 mtrs band and feeded with paralell line with ZMATCH for tuning on 7, 14, 21, 28 Mhz.
About dimension, you can see my antenna. If you want to work on 80 mtrs band, you have to multiply everything with 2. So, depending the space on the building and your local regulations. About mast, you cand use a fiberglass mast from Spiderbeam.
About your question, what level is better for you, I'll prefer the highest possible.

Yakov,
Yes, I have read about wooden buildings. Unfortunately, we're talking about New York City, where most of the apartment buildings are made of concrete, brick, or brownstone. The reason I'm asking is because I'm apartment hunting right now.

Cristian,
Thanks for the tip about Spiderbeam. I've looked at two apartments so far.
One of them is on the 5th of 5 floors and has roof access. However, it is
surrounded on 3 sides by taller buildings and has a clear line of sight on 1
side to the West. I'd prefer a clear line of sight to the eastern horizon
for DX if I was forced to choose one direction because I'm in New York City.

Hi Frank,

I suppose it's very hard to be hamradio in NY city. Check your regulation about antennas, if you can obtain permit to install on the roof and check how much space do you have. You can look for mast on Spiderbeam web site.

http://www.spiderbeam.com/home/index.php

Hi Frank,

From my personal experience, I live in Toronto, Ontario on the 30th floor of a 31 story building. Reinforced concrete construction so lots of rebar metal. South facing balcony.

Because of the construction type, indoor antennas are useless. From the balcony I use a MFJ-1788 40m - 15m small loop antenna.

I can work DX when condx are good. I'm not really a dx chaser and mainly concentrate on North America CW work on 40m and 20m. I am pleased with my results. I would like to build a broadband rx'ing loop because the transmitting loop is very narrow and I like to scan the H.F. band.

80m and 160m would be more difficult in an apartment building but I know of a couple local hams doing that. They have permission to string long wires to other nearby buildings owned by the same landlord or have permission to put up antennas on the roof.

73,

Tom Curtola

6812. RE: [loopantennas] operating from apartments

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-08 15:50:44 UTC
From: D Anderson
Topic: 6803 Message: 6812

I've operated from a metal 12 story bldg.
When on 5th floor I had a crushing signal 40-10m
When I was on the top floor (same antenna assy) my signal was poor.
I used a hygain 18v style antenna stuck horizontally out the window.
Mounting was done with a C-clamp attached to wood rail.
Tuning was done by tapping loading coil at base and I used a Z-match-to-gnd
and VSWR meter(zero refl power).
My gnd was not great but I used some short wires to anything metal I could
clip onto.
I ran 500w and had a great sig on 20+40m, mainly helped by the bldg's metal
ground plane!
At the bldg's top (after I moved), gnd plane wasn't good so my sigs were
poor.

Hope that helps - Dave K6QDD

Subject: [loopantennas] operating from apartments

Greetings fellow hams,

Thanks for having me. I want to pick your brains already :)

1. If you could choose a city apartment rental floor from which to
work DX (and local) on all HF ham bands to include 160m (and VHF &
UHF), which floor would you choose? This includes operating from
indoors, and from a balcony or fire escape. Let's assume for
simplicity's sake that any floor you choose has a clear line of sight
to the horizon in at least one cardinal direction. (The apartment
building isn't surrounded on all sides by taller buildings.)

2. Which floor would be the lowest floor you would consider?

3. Is there such a thing as a floor that's too high for good
radiowave propagation? (Let's be reasonable. There is no Tower of
Babel Apartment Complex in this city ;)

4. What if you could choose any rooftop from which to operate from
time to time? How high would your rooftop be? How many stories?

5. What kind(s) of antennas not permanently installed would you use?

Thanks in advance.

73,
Frank

6814. 160 loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-10 14:12:30 UTC
From: wrenchwerk1
Topic: 6814 Message: 6814

Hi, just joined thanks for the opportunity. I have an 80 meter loop. works well but I want more, as I always do. I will be adding the correct amount of wire to go to 160 very soon but wanted to play with heights and slopes. I am at ~15' now and thought perhaps 1/4 to 1/2 wave would enhance receive and transmit capabilities, as well as SWR which is a problem on low freq. now. I have read a lot on this and know that horizontal and vertical installation radically changes takeoff angle but? Any thoughts or experience would be a great help once I get the ladder out. Thanks 73 KD8HSK Bill

What size loop are you using, full size or compact loop?
If you can get the loop mounted vertically the losses (or gains for that matter) would be significant.

I use 1/4 wave wire magnetic loops based on Ben G0CWT's patented feed system and the 80M version works great on 160M when I modify the impedance transformer.

Give his website a look: http://g0cwt.co.uk/magloops/

I built and had his 80M version up and running in 2 hours.

I meant losses would be reduced while overall gains would be significant.

Since we are talking wire loops and not magnetic ones, the old formula for wire length is as usual 1005 / f (MHz) . So you are looking at around 500 feet plus. If you use thin wire it has less capacity to ground than thick wire.Therefore the detuning effect is a little less when you are relatively close to the ground. At any practical height it will always give you a "hot air balloon" type of radiation pattern and will toast worms if it is too close to the ground. You really need to adopt the suck it and see technique with an antenna analyser by starting with your loop cut for say 1850khz and then see where it rattles best. A quarter wave (remember to include the velocity factor) of 75 or 80 ohm twin will present something close to 50 ohms at the shack end. The usual impedance of a full wave wire loop is around 110 ohms at its feedpoint.
Good luck. Mike Holden, G4HOL

From: wild_bill_yonder
Topic: 6814 Message: 6820

Hi all! Here's a quick question. Earlier this year we purchased an old house sitting on a bit more land than we have at present. I wanted to put up a 160m loop, but once up, using the trees most convenient, it only amounts to about 120m of wire. I feed it with twinlead, run it through a 4:1 balun and a short (3') piece of RG8 to the tuner (at some point I want to try making a balanced tuner with a 1:1 on the radio side). Other than not tuning 160m, what difference will there be on other bands besides where my lobes will be. I modeled both sizes and I do see the different patterns. I have also noticed that the 2:1 bandwidth on 80m seems to be narrow, but I haven't measured it as of yet.

The antenna seems to perform really well. It's only been a month, and I'm only at that qth after work and I can't spend much time on the air because I need to get the work done at the house! I can tell you, the noise level is extremely low. On most bands it is S1 or less, at least on ssb. Of course, the only things on the electric right now is the radio and the pump for the well. It talks real well into G land and northern Europe, and my first qso was Nigeria. I haven't been on enough to see how it is stateside other than it seems to do quite well on 80m. I just run barefoot.

Well, so much for a quick question! I'm just wonder if I should reduce it to an 80m loop or just leave it alone!

Thanks a bunch!

The best one for top band would be two wavelengths circumference, horizontal loop. Great if you own a ranch ! It should throw a 4 leaf clover pattern at about 60 degrees elevation......rather similar to crossed dipole effect but 3dB better.
In practice, use the biggest and highest available and tune it as one would with a doublet on open wire feeder or 300 or 450 ohm line. Another dodge is to put an auto tuner up in the sky at the feed point, and then the normal 50 ohm coaxial back to the shack. That way it should tune all the hf bands. Wow wouldn't we all like a quiet neighbourhood like yours !

Thanks, Mike! Sounds like, for now at least, I should leave it as it is. Maybe once I get the house done I'll have more time to look the trees over and see if I can get some more length in the air. Now that the leaves are going bye-bye I can see a possible route, but the power lines cross the property and I need to see what I can do and still stay away from them. Unfortunate story making the rounds today of a father, mother and son putting up a mast or tower for new ham grandma that were all killed when the wind got hold of it and it hit the wires.

Last night I got on and heard a guy in Italy calling and gave a shout. Didn't last long, I was only about S5 and down in his noise. After we called it quits I realized that I never turned the power back up after tuning and was only putting out about 25 or 30 watts! I think I'm going to like it up there!

Easily done, I worked 3 W6 stations in quick succession one summer day in the eighties. I was surprised that a half size G5RV did so well. Then, like you, I found out it was just 25 Watts instead of 120 W of ssb. I think we had a few sunspots then. Regards, Mike.

6824. LCR meter

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-18 12:28:06 UTC
From: C. Beijersbergen
Topic: 6824 Message: 6824

In the past we have seen threads in this or other groups about buying or building LCR meters to measure the values of components to be used for building antennas. Ready made items or kits have been mentioned and circuit diagrams heve been made available.
Recently I came across an approach by ON7YD that makes use of very simple hardware, a few resistors and capacitors and PCV software that uses the sound card in the PC. I have not tried it yet, so I cannot support the claims, but I think you would like to know ande decide for yourselves.

Go to:
http://www.qsl.net/on7yd/

select "software"and then scroll down to: "LCR meter".

You could go there directly through:
http://www.rcl-meter.strobbe.eu/

But then you will miss a large amount of other radio and antenna related material.

regards,

Cor Beijersbergen

Seems to me that having to connect your computer to anything experimental just makes your computer vulnerable to ESD damage or worse.

Why not go with a stand-alone LCR meter kit? They're easy to build, pretty accurate and not as expensive as they used to be?

At least if you have to measure a cap that has still some charge left in it, you won't risk frying your computer.

73s,
geo

I don't normally like to respond just to say "me, too", but...

Me, too.

I have also placed the schematic of a capacitance meter in the Files under "Useful Test Equipment". It uses a couple of 555 timers or a dual timer 556, I've built many of them (and sold them, that's why I kept building more). You can use your DMM as the readout, or put an analog meter on the output.
<http://groups.yahoo.com/group/loopantennas/files/UsefulTestEquipment/>

I also put a tentative schematic for a dual 555 inductance meter there. I have -not- breadboarded that one yet.

That is a cool tool and web site.

I bought an el-cheapo Capacitance/Inductance/Ohms and NPN/PNP transistor tester off of ebay for $21 total. They are Chinese made and sold off of ebay. I am sure the unit you recommend is better.

Seach eBay for:

LCR RCL INDUCTANCE CAPACITANCE RESISTANCE METER W/Leads

I own one of those AADE meters but how well does this import meter function? Sure a nice price and seems like a lot of the recent Chinese electronics is high quality with super affordable prices.

Hi Mike and Gang:

I own and use both the AADE and a cheap Chinese import model as described. The advantage of the Chinese model is that it will measure larger inductors that might be used at audio frequencies, switching power supplies etc. The AADE is more accurate, as it uses a higher test frequency. I have often been quite impressed with the overall measuring qualities of the AADE. What is the measurement difference of the two units at HF? That is vary hard to quantify. There are just too many factors involved. I do a lot of building here, so the AADE unit has been a very worthwhile purchase for me. I use both units as required by the use at that moment.

I think it would be worthwhile, like you, to own both meters. That Chinese meter is so affordable. Good to hear that it works well for you. I will be ordering one when I return home. I use my AADE meter almost daily. A guy can never have enough tools or test equipment...hi hi

6833. Re: LCR meter

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-21 18:21:06 UTC
From: gmcjetpilot
Topic: 6824 Message: 6833

I'll tell you this. The first Chinese electronics I bought was about 2 years ago AND COULD NOT BE HAPPIER. I got a Degen DE1103 portable SW radio ($80), 100Khz to 29.99Mhz plus the BEST FM STEREO SOUND I HAVE EVER HEARD (with headset). The radio has a single speaker and is super compact, so for stereo FM you need cans. I use Sennheiser HD280 Pro's. The Best stereo I have heard with fantastic sensitivity and range. We all think BIG is better with SWL or Ham gear. This is ONE of the best RADIOS you can buy for under $600. IT IS THE BEST RADIO BAR NONE YOU CAN BUY FOR UNDER $100. It beats all the radios in my opinion in the same category at four or five times the money. This is common wisdom among SWL fans who use portable radios, the DE1103 (or KA1103) is a winner.

The DE1103 can be held in one hand, runs on batteries for almost 10 hours and has self contained antennas (a very long telescopic antenna and loop stick). The DE1103 plugged into an external antenna, like the active loop I bought at the same time for $20, the TG34, performance is very close to the RX320D on a random wire. The TG34 is a generic version of the Kaito KA33 and Degen 31MS. They go for $30 but got a deal on mine with the radio. AMAZING PERFORMANCE AND UNDER $100. The Degen DE1103 also comes in the Kaito KA1103 brand, which is the US import name brand.

The Chinese often throw in extras. The DE1103 came with 4 NiMh AA's, wall-wart power supply (which charges the batteries inside the radio), 30 foot wire antenna, storage bag. I got the radio, optional TG34 antenna and optional leatherette soft storage case for about $100.

I also find the Chinese eBay vendors responsive and cooperative. Their English is actually pretty good. You get some Engl-nese some times, but they are cooperative. The LC meter I got had a yellow rubber cover. The picture showed blue. I was not too upset, but I wrote them to just point that out for the future. They gave me 10% off the already low price.

Shipping time may be a little long but not bad. You just can't expect it in 2 days. Depending on what it is, it can take more than a week. I really forget how long things take. What I can tell you, I get stuff faster from China than Canada! Orders from Canada can take forever.

I bought some NiMh batteries. I have got great deals on charger and battery packages. The battery performance is GOOD and compared to Wal-Mart, it is 1/4th the price (including shipping). I bought some 3000mAh Ni-Mh knowing it was not likely to be that much. Well I have

no idea what their capacity is. I doubt 3000 but they work well. I find they are getting better with time. I may need a better charger that does some fancy higher voltage cycle. Regardless they are a steal at twice or three times the price.

Since buying the above radio and batteries, I bought a LC capacitance/inductance meter and oscilloscope probes. Build and performance are good. Fantastic lab quality accuracy gear built to last decades under heavy use? No. Serviceable and accurate enough? Yes, especially at the price.

I have a friend who bought a bench Freq counter for less than $100. It looks very nice. It came out of Hong Kong. I got a used HP Freq counter for less, but his has way more features. Accuracy? I don't know but I bet it's GOOD ENOUGH for radio work. They have a bunch of hand-held battery powered antenna based freq counters as well, which intrigues me; they go for about $50-$60.

Signal Gens. Another friend bought a Chinese S/gen; it is nice. They go for about $120 total. When it comes to basic signal/audio Gens you have limited choices. You can buy a boat-anchor, big tube job. Nothing wrong with them, but chances are you'll need to "Re-Cap" it & celebrate it. Also they need to warm up to get good accuracy and min drift. Than there are solid state signal Gens. Cost of a used signal gens can go from $60 to $12,000. I have never used the China made signal gen, but I am sure they are fine. I'd hope it would not need repair, but if they come with schematics and parts list (generic not proprietary), I wouldn't worry about it.

What I would like to see is a cheap modern task specific sweep/marker signal Gens for radio alignment work (I.F. of 455Khz and 10.7Mhz). It is hard to find good stuff that works. Either you need some rocks (Crystals, Xtal) or the sweep/marker is for other higher freq applications. The old good gear is hard to find at a good price. Even than chances are it will need to be fully restored, caps, resistors and so on.

Tube Audio AMPS: The Chinese have a few Valve amps I lust after. I have been SO TEMPTED to buy one. They sell them for less than what I could make one for from parts. The sound is very good from what I read, but some times they need some small modifications to really make them sound fantastic. However overall they're bargains. For the money the Chinese Tube amps are clearly a deal. I have heard only a few complaints about build quality. Some have said there were extra parts in the amp, not in the schematics on a few models. Some models are fine out of the box. Some need a few mods. All of them end up sounding fantastic from what I read about them. $400-$500 Chinese tube amps compare to tube amps which cost $2000-$12,000). Of course I think it is crazy to spend thousands on a stereo amp of any kind, but than I am not an Audiophile (fool with money who thinks they have a golden ear and spend $100's or $1000's extra if the word Audiophile

is added). Who am I to say how people should spend their money.

Bottom line on Chinese test gear. Research, shop around and ask questions. Also the Chinese undercut each other. Right now the LC meter I have is flooding eBay. Some go for Buy Me Now $20 total, some $24. They have other makes that go for $30-$40 that might be better. If you spend a little more you can get a DMM/DVM combined with a LC meter that reads volts, ohms and temperature as well!

PS I have seen some color storage oscilloscopes as well.

6834. Spacing Between Loop and Rotator

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-23 10:13:04 UTC
From: VK1OO
Topic: 6834 Message: 6834

All,

Another question. I'm thinking of mounting my octagonal loop above an antenna rotator. Theory suggests keeping magnetic loops away from metal objects. So the question is, how much space is required between a loop and a rotator?

Mike
VK1OO

6835. Loop Size

Topic: 6835 Message: 6835

Hi,

I'm building an octagonal magnetic loop. I'd like to use it on 40m and higher frequencies.

The theory suggests:
For highest efficiency, the conductor length for a small transmitting loop antenna should be greater than 1/8 wavelength.
To avoid self-resonance, the conductor length for a small transmitting loop antenna should be less than 1/4 wavelength.

I've got enough copper tubing to make a loop of about 1.2m "diameter". This would be good for 40m because of the larger area, but would be greater than the desirable 1/4 wavelength on higher frequencies. So, the question is, do I reduce the "diameter" to make the loop more suited to higher frequencies or keep the full length for 40m?

As long as your variable cap has a low enough minimum capacitance, it'll work just fine on the higher bands. The larger loop will be more efficient on the lower bands than a smaller loop. Bigger is better...hi hi

I ran a loop on 1750 meters for many years that was 24" from a steel dog kennel. The loop ran along the kennel for 12'. It worked just fine. I wouldn't worry about a tiny rotator under a HF band TX loop.

You have the right idea. I design my mag loops for two bands at a time for most efficiency although I load them for lower than intended frequencies with very good results. My 40M loop is 1/4wave minus 5%, that help keep away from self resonance. I use that loop on 40, 60, and 80M.

Good luck, I'm certain you will be absolutely impressed with these loops.

While you're at it, give this web site a look:
http://g0cwt.co.uk/magloops/

I built the 80/160 version with excellent results.

The AADE is tough to beat, I have one. It eats batteries because I always leave it on after measurements are made. The meter works great, the battery problem is operator error I suppose::>

Be aware that some inexpensive meters don't cover the low and high capacitance/inductance ranges well. And, all will be marginally useful on toroidal (or any other type of coil that uses anything other than air dielectric). The error can be significant. This happens with all capacitors and inductors unless they use air dielectric, although capacitors are less affected than inductors. Basically, you need to measure the inductance/capacitance at the frequency you will use it at. For instance, a given toroidal inductor that measures 10 uH on the AADE (at 10 KHz) will actually be 14 uH when you test it at 3.7 MHz. It's always best to measure toroidal inductors at the frequency where they will be used, not at audio frequencies.

Even non-air dielectric capacitors vary in capacitance as the frequency changes, although not quite so much as toroidal inductors do. I recently became interested in making capacitors for my own use, and had a tough time finding frequency characterization data for teflon.

Also note that all capacitors vary in capacitance when biased with a dc voltage, especially electrolytic and tantalum. And, inductors vary as the dc current passing through them changes.

From: mrkeeks
Topic: 6841 Message: 6841

I asked on the Wellbrook group but got no replies so I'll try here.

Has anyone or is anyone here using an ALA330S?

Good points?

Bad points?

Because of where I will be living a wire antenna is pretty well out of the question but a smaller loop like the 330S would fit perfectly.

I am a Utilities DXer...mostly HFDL and mostly hunt in the 4mhz to 18mhz range.

Ken

All I can say is I've yet to meet someone who owned a Wellbrook product who complained or felt they got less than their money's worth. It's a quality product with quality support

I prefer to build my own stuff (and I have built a couple of broadband loops that are close to Wellbrook's specs but not quite there) but if I were to purchase a commercially built antenna one of the Wellbrook units would be it

I'd bet once you get one you'll be working lower frequencies too (NDBs, NAVTEX) because you are probably going to find there is suddenly a whole bunch of stuff down there you could never hear before

JR

I have lusted after the Wellbrooks for awhile. I plan on getting one. Occasionally you see them for sale, and they get a good price. Wanting one I did my research and read every review I could find. The book "Passport" is a SWL book that comes out annually I believe. It has all kinds of info gear and SW radio schedules. The year I have reviewed the Wellbrooks (both ALA330 and ALA1530). The ALA1530 is the object of my desire.

I just never heard a bad thing about them. The COOL trick is they get broad band coverage with out TUNING!!!! That is cool. One down side of course is powerful BCB stations bleeding into the SW band. That is where the ALA330 comes in (rejects BCB).

The down side of LOOPS to me is always having to tune them. That is why I will always have at least a RANDOM WIRE to augment a loop. Because of tuning and directional characteristics of most LOOPS, they are not great for scanning the whole SW spectrum. To be fair no antenna is optimal for a broad band of freq. However Wellbrook seems to have done it a good job. If I know the freq, location and time of a station I want to target, a loop is killer.

The biggest complaint of the Wellbrook I can find (besides cost) was they come somewhat incomplete with out cables and connectors (I recall). However as far as performance, I heard no complaint. In fact in demanding environments it was the only antenna that worked for some folks (reducing RFI). I guess cost is high really the main objection, but you get what you pay for. Think of all the time and effort you take to make a DIY antenna. The antenna is more than half the radio, so I don't think cost is too bad. What is bad is the buying power of the dollar.

As far as DIY I have a killer design for a remote tuned SWL loop that is all electronic. The antenna needs to be feed DC power and is tuned by a variable capacitor or varactor (varicap). Unlike the Wellbrook you need a little control box to tune it. The good part is I can make it for less than $100. The most expensive part is getting a nice 1-meter metal hoop. I could use a hula-hoop with a wire in it, or use PVC pipe and make the loop square. Any way I just have to build it.

IF ANY ONE KNOWS WHERE I CAN GET A ONE-METER (or less) HOOP MADE OF ALUMINUM OR COPPER LET ME KNOW.

George

I live in the United States and got two defective antennas from Wellbrook. Sending them back cost me quite a bit of money and hassle. If you're in the the U.K., then your risk is quite a bit less. Wellbrook would be wise to sell their product through Universal Radio or Grove.

Hi !
Check this amplifier:

http://tupala.mine.nu/utility/fkuvat8/9v1vv.jpg

It is field tested to be quite good versus ALA100.
In some cases even better.
Parts dont cost much and easy to build.

Just to be clear, if you have the money GET IT. Personally I like the ALA1530S+ better but the ALA330S. Both are great (from what I read, don't have one). The 330 is fine if you are not interested in LF and MW. As I said if you are close to AM MW BCB station, they can mess up SW with the ALA1530. If you just want 3Mhz-30Mhz, than go with the ALA330. If you want to go down to 150Khz than the ALA1530 is the way to go. I think the ALA1530S+ is improved and has less problem with strong AM BCB stations.

With that said you will need a pole, rotor system, coaxial cables, adapters to from from BNC to radio or make a cable with appropriate connector. It comes with the antenna, power, electronics box and that is about it. I have seen people hang this up in a picture window or set it on a fixed direction. However rotor is really needed. The point is it does not set it self up in minutes, and you will have to spend another $100 or more to get it going.

They give you fairly simple bare bone instructions, but it should (MUST) be away from the "Radio Shack" (house) a specific height above ground. I plan on roof mounting mine. However I have heard this might be an issue. Some mount in attic with good results? One thing for sure is people with wicked RFI problems find the Wellbrook is a miracle antenna for their noise problems.

George,
Regarding the appeal at the end of your posting.
It is hard to beat a 27 inch diameter Aluminium cycle wheel rim.
They can be had as scrap at a cycle workshop even if they
require a little attention after a knock.
72, Brian, G0NSL-QRP.

6852. 30 foot loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-10-30 21:55:11 UTC
From: Bill McGraw
Topic: 6852 Message: 6852

I just taped up a square 30 foot vertical loop on my east office wall, used a V-cap with it to help tune it but seemed not necessary. It worked nearly as well as my horizontal 44 foot loop at the ceiling. I don't know why but I haven't heard any any strong SSB signals on 80 meters in several weeks. 6 MHz stations, China and Cuba come in strong. I haven't heard anything on 20 meters with this radio.

Will someone tell me how best to make a lead-in to my radio (RS DX 398)? Can I just twist some stranded wire together? Do I need to ground the loop? I grounded the horizontal loop, actually a OCF horizontal loop of sorts, one end to my outside ground and both ends fed into a sterio 1/8" plug to the radio.

Good tip! Aluminum bike rim. I will definitely look into that.

The only down side of the rim may be EYE appeal, may be? It might look great, even paint it black. I have the antenna police in my HOA "Home Owner Association" controlled neighborhood. (Last time I buy a new house with HOA). Because of the by-laws I can put up an antenna that is 1 METER or less in dia, so 27" is perfect. The rule is no doubt for Dish antennas, but I am going to push it. Let them sue me. I don't have my ham but I'll get it. Than I claim Fed immunity.

I still don't want to push it too much, so I need to make it as "stealth" and "Pro" looking as I can. I think painting it black would be cool.

The idea of a strip of aluminum rolled onto a hoop might work?

I found professional aluminum hoops used by performing artist (e.g., circus) were about $50 each. I was also thinking of a plastic hoop (like a hula hoop but thicker walled) and running a wire in it, preferably Litz wire.

Hi Bill,

What I found that works really well is hooking my loop wire into a balun, I think a 9:1 type that is used for cable tv. On the radio side is a cable wire from the balun that goes directly into the radio with a pal connector, or if you need to, some other adaptor. This hookup reduces radio noise virtually completely and the signal doubles or even triples. It works great for me.

Regards,

Frank

George,
Thank you for the mail.
Your home situation is quite common over here with lots of the new housing estates, not even a washing line in sight hi!
I use my loop indoors as it is mounted on a photographic tripod using the pan & tilt head to give rotation in two planes, works fine.
Now there's a thought, if you were to mount the loop on a tripod with a black cloth thrown over it circa 1800's style they would think it was just a big lens for bird shots hi!
Somewhere I read that flagpoles are one antenna trick in the US, who could object to you attending to the flag morning and night, a true patriot !!!!!
If you had one with the ' H O A ' logo on they might even buy it for you hi!
Regards,
72, Brian, G0NSL-QRP.

Hi,
If you buy a Hula Hoop, you can wind a substantial lenth of wire around it to make it resonate, say on 40M, Another trick is to buy a kids 'Slinky and thread it so that it forms a loaded coil around the Hula Hoop , use some sticky patches to hold the slinky in place, Again should resonate on 40M..
Best 73s.

6859. Feed impedance and filtering for a small receiving loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-01 03:23:26 UTC
From: david feldman
Topic: 6859 Message: 6859

Want to build a wideband receive loop antenna, about 1.5M diameter, with preamp located at the feedpoint. Put one together last winter (see URL mentioned at end of this posting) like this (I used PVC tubing for structure, and RG6 coax using shield/center shorted together as the conductor) but preamp was overwhelmed by AM BC station about 1km away. Still need a loop receiving antenna (high RFI from neighborhood DSL and other garbage around here), so considering how to mitigate the AM BC interference.

The loop itself (no preamp, just the circle of wire) has ~1.3K feed impedance (according to Autek RF-1, the only instrument I have to measure this) at 3.5 MHz, dropping to ~1K at 4 MHz, and continuing to drop as frequency goes up. Frequency range of interest for the antenna is 3.5-15 MHz. As an aside, the loop itself is resonant with ~50 ohm feed impedance around 30 MHz (but that's not the application I have in mind.)

So here is my thought - use 16:1 balun to transform the loop's basic feed impedance closer to 50 ohms, then feed through a high pass filter with cutoff ~3 MHz (to reduce AM BC band signals but minimize impact on 80M and above signals), then a wideband mmic amp (50 ohms in/out, ~20 dB gain) to drive signal back to shack receiver.

Is this a reasonable way to approach this? Other ideas, resources, suggestions or comments would really be appreciated.

By the way, this is the URL of the original antenna I built, and the basis for the idea to build a version that has high pass filter between the loop and the amplifier:

http://www.qrss.thersgb.net/active-loop-receiving-antenna.html

Thanks,

73 Dave WB0GAZ wb0gaz@hotmail.com

Oops - realized after all this that a major problem exists in my antenna analyzer (high Z into a small loop didn't seem right but....); Will re-post once I work out the correct feedpoint Z for the loop! In the meantime, other than the error in feed Z, any pointers on high pass filter in small receive loop would be appreciated,

Dave

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

6862. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-01 13:27:46 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 6862

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

I did an extensive amount of impedance measurements for loop antennas some time ago, which were then used for a series of receiving and transmitting antenna designs. One of the designs, which is remotely tuned using a pair of varactors, is at:

http://www.home.earthlink.net/~christrask/Paper011.html

and an indoor version is at:

http://www.home.earthlink.net/~christrask/Paper018.html

You'll notice that the loop impedance can be seen as a resistor in series with an inductor, plus a parallel-resonant RLC network if you encroach upon the first resonance. For wideband usage, an acive loop antenna is pretty much limited to interfacing with a high input impedance amplifier as the first stage, which is not going to make your AM BCB station interferance problem any easier.

I did make an attempt at wideband passive matching of loop antennas, which is at:

http://www.home.earthlink.net/~christrask/Paper010.html

where you can see that the potential for a passive solution is not on the horizon. One possible solution is to use an active negative inductor, but I have yet to come up with a design that is suitable for applications such as this.

John's design is a useful and practical approach to wideband loop antennas, however the high amplifier input impedance makes any filtering difficult. You could try implementing a

balanced filter section between the antenna and the amplifier:

Don't forget Copper tubing from the plumbing section of the local
home improvement store. You can go with the soft-drawn and shape
it into any shape you like, or you can go with the hard-drawn and
use elbows to put it together.

> The only down side of the rim may be EYE appeal, may be? It might look great, even paint it black. I have the antenna police in my HOA "Home Owner Association" controlled neighborhood. (Last time I buy a new house with HOA). Because of the by-laws I can put up an antenna that is 1 METER or less in dia, so 27" is perfect. The rule is no doubt for Dish antennas, but I am going to push it. Let them sue me. I don't have my ham but I'll get it. Than I claim Fed immunity.
>
> I still don't want to push it too much, so I need to make it as "stealth" and "Pro" looking as I can. I think painting it black would be cool.

>
> I found professional aluminum hoops used by performing artist (e.g., circus) were about $50 each. I was also thinking of a plastic hoop (like a hula hoop but thicker walled) and running a wire in it, preferably Litz wire.

You can do that with Copper plumbing tubing, too. Just make sure
it's not an electrically complete circle, since that would act as a
shorted turn.

Dave

6865. Re: Feed impedance and filtering for a small receiving loop antenna

Chris, thank you *very* much for passing along your papers; I'll read them carefully. I had thought about a varactor tuned loop (and picked up some diodes this last spring) but didn't explore further at the time, so this will certainly be helpful to understand.

I'll post back any results once I can get some experimentation underway.

Thanks again very much,

73 Dave WB0GAZ wb0gaz@...

6867. TL and QL loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-01 22:47:08 UTC
From: Hue Miller
Topic: 6867 Message: 6867

Loop Antenna News and Information ForumThe TL loop antenna is no longer in production and the link provided, to Quartzlock, provides
an very interesting data sheet
http://www.quartzlock.com/downloads/datasheets/AE30-300_datasheet.pdf
for their product, However, NO PRICE information provided at all, which I think a very bad sign,
it means I think, "If price is that important to you, look elsewhere, fellow."
Besides, the QL antenna looks not very impressive, certainly nothing impressive when compared to, say, the Wellbrook.
I was very pleased to see the RadCom RSGB antenna project link - I had thought for a long time I would have to buy a back issues compilation to find this.
I also wonder if instead of coax output cable, in the interest of maximum noise rejection, it would be worthwhile using twinax, or perhaps just doubling 2 coaxes bound together.
A moderate impedance mismatch, say 2:1, in this application has no bad effects, I think?
BTW, I note the Grahn (Deutschland) loops in the remote located form, do not work above 4000 kHz, and the one that does tune to 30,000 kHz is a desktop type, not remotely located. This is not what most of us are interested in.
-Hue Miller / Newport, Oregon, USA

Topic: 6852 Message: 6869

You can twist the wires from you loop to your phono plug. Several turns per inch should suffice. You should have a nice broad frequency response with that set-up.

John

I just taped up a square 30 foot vertical loop on my east office wall, used a V-cap with it to help tune it but seemed not necessary. It worked nearly as well as my horizontal 44 foot loop at the ceiling. I don't know why but I haven't heard any any strong SSB signals on 80 meters in several weeks. 6 MHz stations, China and Cuba come in strong. I haven't heard anything on 20 meters with this radio.

Will someone tell me how best to make a lead-in to my radio (RS DX 398)? Can I just twist some stranded wire together? Do I need to ground the loop? I grounded the horizontal loop, actually a OCF horizontal loop of sorts, one end to my outside ground and both ends fed into a sterio 1/8" plug to the radio.

6870. Height versus lenght in loop antennas, and direction.

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-04 09:55:33 UTC
From: Marc Coevoet
Topic: 6870 Message: 6870

Hello:

Suppose the Height/lenght > 1, will the antenna be more directional
than with a Height/lenght <1 antenna??

My idea is that n,ow I'm always using a circular loop 35cm/1 feet to 3
feet, 1 meter, and I'm thinking that a square loop/rectangular loop
might be more directive. Would that be true??
(making onde is not such a big work).

BTW: in the ultralightdx group(yahoo), they are using radios with a
silabs chip in it, like the kchoibo kk-S60L, or the tecsun pl-310, that
canb set am narrow/wide to 1, 2, 3, 4 or 6. Fm is very good too, and
maybe better than the sony digitral hd radio.

All,

I'm now looking at the coupling loop for my 1.2m diameter 25mm copper tube loop. Which is better and why - a shielded Faraday Loop or just a plain wire coupling loop or even a gamma match? What's the difference and is there any test reports available measuring and comparing performance?

Many people have becomd frustrated with the difficulty of tuning a loop
with both Faraday loops and Gamma matching. I decided to try a different
approach using a series of wideband transformers, and the results were
repeatable trouble-free tuning:

Topic: 6871 Message: 6874

I have used all 4 methods including using the toroid feed.

I've seen no difference between the Faraday shielded feed loop and the bare wire loop, so I use bare wire loops these days. The bare wire will handle more power for continuous duty modes like digital/rtty. The toroid feed method seems to overheat with 100watt continuous duty (at least my T240-43 ferrite does).

I've used gamma method and it may actually be the simplest method.

The variable I have noticed that introduces problems is the loop height above ground. The lower the loop is to ground the larger the feed loop needs to be. I built a 20M loop in the basement and the feedloop was nearly 1/3 the size of the main loop to achieve a 1:1 SWR when testing. When I moved the loop to the attic I needed to reduce the feedloop size to the original 1/5 size in order to get a 1:1 SWR.
Also, the lower the loop to ground the longer the gamma match feed will be. With the toroid feed method you just increase or decrease the number of turns on the coax side. I made a toroid matching section with a switch that selects the turns ratio I need so I can adjust the impedance to match where ever I mount the loop.

I would go ahead and try the bare wire feedloop first and be ready to change the loop size and also the shape. I find I need to compress the feedloop into an oval to achieve the 'perfect' 1:1 match.

Good luck and happy experimenting! You will like the loop results!

atd

Hi All

I'm looking at a Wellbrook AL-330S. I know they can be mounted on a rotor and show some rejection. Do they reject when the loop is facing the noise or on the loops "edge"?

So is it the "O" or the "|" side that rejects?

Thanks
Ken

I'm sorry, I did a reversal of position, but to be sure, see the drawing.
Small loop antennas have patterns opposite those of large loops. The minima, or nulls, are perpendicular to the plane of de loop, while the maxima are off the ends. Figure shows the directions of maximum and minimum response. The loop antenna is viewed from above. the nulls (dotted lines) are orthogonal to the loop axis, while the maxima are along the loop axis

Hi,

The radiation/reception pattern of a large loop is maximum perpendicular to the loop plane with nulls off the sides. Small loops (which includes the Al-330s) are opposite .. e.g. maximum off the sides of the loop and nulls perpendicular to the plane of the loop.

Eduardo,

What u say is correct for large loops ... eg 1/2 wavelength or
larger. Small loops ... tuned or untuned are the opposite. With a small
loop "0" gives maximum rejection/null ... while "I" gives maximum
reception. Of course the null is sharp and maximum reception is broad.

We are either 100% correct or 100% incorrect hi hi ...

Jim, VE3CI

reason is that small loops responds to intregal H*dl=N*i responds to current and in fact we have a delta H across the loop on a line of Max H

hitting loop is Hmax and other side of loop is Hmin and delta H = Hmax - Hmin

****

for larger loop we get the voltage relationship e= N *2 *Pi*f* Phi= N*2*Pi*f*B*A= 2*Pi*N*u0*ur*H* A

where ur=1.0 for ail
u0=4*Pi*10^(-7)

and A = loop area in m^2
and Phi in webers
Phi = B*A

best Paul

Eduardo,

What u say is correct for large loops ... eg 1/2 wavelength or larger. Small loops ... tuned or untuned are the opposite. With a small loop "0" gives maximum rejection/null ... while "I" gives maximum reception. Of course the null is sharp and maximum reception is broad.

We are either 100% correct or 100% incorrect hi hi ...

That link doesn't work for me, it looks like a link to a file in your Yahoo mail? Or you linked to a location in Files, those only work for 30 minutes to prevent file leaching.

I found it:
<http://groups.yahoo.com/group/loopantennas/files/Nulls%20loop.doc>

It is better if you don't use spaces in file names. You must replace every space with %20.

I also strongly recommend against posting scanned/raster images inside a DOC file. Just upload it as a JPG or GIF, it is easier to view and the file is a lot smaller.

6887. Sprial loop 48 x 48 inch

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-10 10:42:57 UTC
From: Michael in Suffolk
Topic: 6887 Message: 6887

Hi. I have just made a 48 x 48 inch sprial loop { looked at PICS could not see very many} and am having tuning capacitor - or wire problems.
 I also have a 24 x 24 sprial loop with 11 turns and that is giving no problems at all. OK the set up here is I have about 7 variable metal VTC caps and have tired them all in either paraible wire up or just one vain and earth side all these either having 8 x 11 or 13 x 13 vane or a combo of 8 min to 16 max vane.
 I also have some old flat bakerlite types dylictric! from the 1950 or before, and only ONE of those works great with one wire to the main tuning vanes and the other to the other side, full tuning with this useing single stranded pvc covered wire, tuning is from 470-1.800.
 THe 48 x 48 inch sprial - Now when I put on any one of the METAL caps the tuning will not go down the even 1.610 all of them stop at about 1.530 khz, Yes I have put on one turn, taken off a turn, total being either from 6-7-9-13 used one side of a vane set and so on, made the wire spacing wider - made it closer to no avail, could it be the 24 strand wire that is the problem, as on the 24 x 24 sprial loop it is single strand, ...help its driving me crazy. PICS of my loops and VTC are on skywavemw not good at giving a link as not very much up with PCs, but you just might find me I hope. Mike UK Bungay Suffolk.

6888. Re: Loops null direction

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-10 18:06:53 UTC
From: gmcjetpilot
Topic: 6875 Message: 6888

The sides or the loop (the hole or "O") is the null

The edge "|" is the Aim

http://www.mindspring.com/~loop_antenna/edgewound_reception.gif

" The pickup pattern is shaped like a figure eight. The loop will allow signals on opposite sides to be received, while off the sides of the loop the signal will decrease or be null-ed out. The nulling feature will allow you to remove a local station on a frequency and pick up another on the same frequency by removing the local signal. A loop may have an amplifier or may not."

NOTE: The actual pattern is VERY COMPLEX, three dimensional and affected by its surroundings and ground.

http://www.pa0sim.nl/circular%20polarization.htm
http://www.pa0sim.nl/loops%20in%20real%20life.htm

You can AIM at an offending STATION offending station or noise and detune the loop for that Freq, to NULL that signal, using broad reception (of lower gain) off the side, Or turn a loop null side to block signals. Some times 45 degrees will do both block and gain.

You can use two or more loops (an array) and do all kinds of NULL and AIM to hear a distant weak stations while rejecting noise and stronger local stations.

http://www.pa0sim.nl/dual%20loop%20system.htm

This is what makes loops so interesting and powerful, not to mention they are WAY more compact than equivalent "Long Wire" antennas. Of course loops are best at LF, MW and SW/HF. At the VHF freq and UHF things change. The wave length is so short a 1/2 or full wave length whip or wire antenna is practical. Also because VHF and UHF tends to penetrate the ionosphere (not skip off) you don't get SKIP or sky waves, it becomes LINE OF SIGHT.

Keep in mind depending on the design of the loop the null can be deep or shallow. The Wellbrook has off side reception, just not the same gain. I suspect this is because it is an ACTIVE loop for one.

Also SOME signals come from the SKY, so no matter what way you have it pointed the signal is coming down on the top of the loop or EDGE. Some people will tilt their LOOP (usually big manually manipulated loops) on a gimbal. The TILT or azimuth can block local signals and I assume get a SKY wave better, improve gain, depending on the angle the sky wave is.

Keep in mind there are PASSIVE loops and ACTIVE loops (amplified).

NOTE: On a loop stick, a ferrite bar with wire winding, it is some what opposite. The longitudinal axis of the ferrite bar is the AIM and the side, (edge) of the coil winding is the NULL.

dear brian

the optimal shape for a loop is a rectangle with rounded corner

the German army used an oval shaped profile

it would be as if you had a circle and compressed at the top so the one ends up with a fully rounded sides and flat at the top and bottom

so likely the above is better than a square for diamond

you need the rounded corners according to the theory

what I cannot remember now is whether the above applies to only small loops yes I think it is small loops

what is also interesting there is an olde swedish patent on having two loops offset by something like 10 or 20 degrees for accurate direction finding and extra gain I think with the extra loop

it is a US patent from like 1933

anyways hope that helps

other likely know much more than above
best wishes
Paul

dear brian

just looking at some pictures here the us marines used to use double diamond loops

the german army field direction finding from wwII used crossed diamond

the us army uses double circular loops as well as some english double loops

again the present german army uses the flattened double loop (n=2 turns) in that flattened top and bottom with full radiused corners (sort of 3' high by 5' wide) rough dimensions

so I guess diamond more than square

Would the most efficient be circular??

It is "shortest path"/ "maximum suface".

When the loop is fed balanced, the null is ALWAYS perpendicular to the plane of the antenna.

If you feed it unbalanced, the null moves, or rather diminishes. As you approach the first parallel resonance, the resonance the null will disappear entirely. Above the first parallel resonance, the null will return to being perpendicular to the plane of the antenna, but the phase will be reversed. As you approach the first series resonance (between the first and second parallel resonances), the pattern will rotate.

I learned this while doing extensive ELNEC/EZNEC simluations of single-turn loops for my 2-part series on active loop antennas in the March 2007 issue of QEX. I did it to emphasize the point that loop antennas should ALWAYS be fed balanced.

I would certainly hope so. The schematic I have for the WL 1030 shows a transformer as the first element. It has a grounded centre-tap on both sides, which is proper design practice for the task. I'm told that the schematic I have is that of a third-party design, but I've never gone to the trouble of verifing that.

Wellbrook loops have a good reputation for performance, so I would assume that they are centre-fed as per the WL 1030 schematic that I have. Myself, I don't care much for wideband loop antenna designs that have high input impedance amplifiers as such a design practice is an open invitation to both noise and interference. But, people seem to have little interest in anything that requires additional tuning effort, such as receiver front ends and antennas.

I put a great deal of effort into my remotely tuned loop antennas, and I'm quite happy with the results, especially those with passive matching and balanced varactor tuning. I'm now working on a companion shielded loop design.

I am now living in a detached condo...small house with private yard but rules stating I can't have an antenna or any other object visible above the top of the fence line. A loop like a Wellbrook AL-330S seems like my only alternative. I also have very limited areas to build my own loop.

I am a SWL/Utilities DXer first and foremost and was told the 330S would fit my needs the best.

6898. ALA1530: no null anymore

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-12 11:24:53 UTC
From: Dominique Kremp
Topic: 6898 Message: 6898

Hi all,

I'm experiencing something with my Wellbrook ALA1530 which is a puzzle to me.

I can't get any null anymore when it's mounted on its pole. The signal is however strong and it receives fine.

When I put it on the ground, it works, the null effect is OK.

Well, it's evident that there is something wrong with the coaxial cable.

How do you explain this ?

Thanks

Dominique

Dominique,

The likely cause is an intermittent open circuit screen connexion on the feeder i.e. the feeder then acts as an omni-directional antenna. However, if this is the case, then you may have an increase susceptibility to locally radiated E-Field noise when the loop is on the pole. With the feeder on the ground, its signal pick-up would be less. Check you haven't got a bad screen connection on the lead from the Antenna Interface to the receiver.

The loss of null could also be due to re-radiation from conductors near to the loop. I have never experience this in practice with single loops. However, re-radiation from conductors can totally screw up Phased arrays of K9AY and Flag antennas.

Kind regards

Andrew

The yard is about 15M long and 5M wide down the side of the house.
There is however a small area at the front of the house with a fence
about 2M high. That means the top of the loop will be a maximum of 2M
off the ground. The side yard has a 1.5M fence along the back. The
side yard is easy to see into while the small area out front is
difficult to see into.

Not sure how many of you have lived in a condo/strat type complex but
you always find one idiot who complains about everything and who
"snoop" looking for trouble. So...I would like to avoid any "trouble".

I've thought about a Wellbrook AL100L/M....but it will have to run VERY
close to ground level. A 330S will allow at least 1 metre height above
ground to the bottom of the loop

6910. Re: Small loop antenna !!!!!

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-15 00:52:56 UTC
From: bm40g
Topic: 6847 Message: 6910

Hi All,

I made my STL out of 1/2 inch heliax. I wish I used 7/8's now, but that is what I would recommend. My loop is 1 1/4 meter in diameter, so its radiation resistance is about 3.4 times that of a 27 inch diameter loop. That is how I thought it would be good, and it is good. I hear dx all over. I usually can hear the station DX station in the pileup if he anywhere in Europe. But hell, it could be even better. It tunes from 6.8 to 15.3 MHz. The match is set for 20 meters with near perfect VSWR, and I need to match it up with a match box down on 40.

If you mount the loop horizontal in the center of a shallow roof it will be hardly noticable. If you have a vent cupola, you might use that to enclose the loop. Horizontal would be OK for sandy soils.

6911. Re: Loop Size

Yahoo group: loopantennas (2008 — 2012)

From: bm40g
Topic: 6835 Message: 6911

Hi All,

I built my loop to be 1 1/4 meter diameter. So if your build a octagon with the flats at 1 1/4 meters spacing it would work similarly. The antenna is well short of 1/4 wave perimeter on 40 meter, buy on 20 its strating to change to the short folded dipole mode and become more omnidirectional.

The lack of efficiency on 40 is not as serious a problem, practically, due to the smaller propagation loss (per unit distance) and the shorter range contacts (typically). In my limited experience. The good null on 40 is beneficial.

Go to the group's page, then look at the left side menu. "Files" are just below the Messages submenus.

Or just go straight to them:
http://groups.yahoo.com/group/loopantennas/files/

You may need to be logged into Yahoo or Yahoogroups.

I enjoy processing stuff to make it store more efficiently. I cleaned up the original 5 pages so the compression would be more efficient and reduced the color levels to 16 shades of gray (4 bits per pixel). I also cut the number of pixels per page in half, since they were beautifully large. Total size as 5 .png files is 561k (less than half the .pdf size). Bob, if you would like to have these to put into a pdf, for size and quality comparison, I would be happy to upload them, here, or email them to you.

From: Silvio
Topic: 6921 Message: 6921

Olá amigos,

Apesar de eu morar no centro de Curitiba, num local com muitos ruídos, eu não perco as minhas esperanças de que a COPEL (Cia Energética do Paraná) possa sanar de uma vez por todas com esses ruídos terríveis que incomodam minhas escutas.

Prova disso foi o último apagão ocorrido neste mes de novembro/2009 durante o qual eu corri para meu rádio Tecsun PL-310 e liguei em OM, conseguindo captar emissoras que antes não conseguia e que durante o curto período do apagão nenhum ruído se apresentou, banda de OM toda limpa, sem ruídos. Isso mostra que do meu apt, 3o andar é um lugar muito bom para escutas desde que esse problema fosse sanado.

Eu já entrei em contato com a COPEL e ela me retornou dizendo que iria resolver o problema em 30 dias, o que, por pessimismo não acredito.

Quero aproveitar e informar meu link para as fotos das minhas antenas para Dxismo, cujo melhor local que já consegui foi na praia de Itapoá, um local magnífico para tal hobby, mas que infelizmente não moro lá, só veraneio.

Aproveito para apresentar minha nova antena loop circular caseira de 1 metro de diâmetro confeccionada com o famoso brinquedo BAMBOLÊ. Levei 1 ano para confeccionar esta antena porque não encontrava um material resistente e ao mesmo tempo maleável e ao mesmo tempo que pudesse ser amarrado/preso ao bambolê e que pudesse acompanhar a circunferência do mesmo. Depois de muita procura consegui encontrar numa loja de couros/revestimentos no centro de Curitiba um papelão com expessura de uns 3 a 4 mm que tinha estas características que eu tanto precisava para poder confeccionar esta valiosa e surpreendente antena loop para OM. Portanto fica aqui a minha dica de antena loop para todos.

Ela tem um rendimento fantástico, mas devido a ruideira presente em meu apt eu estou inclinado a fazer escutas numa pousada no sopé do morro Anhangava aqui na cidade de Quatro Barras a uns 50km de Curitiba. Lá as condições são simplesmente fantásticas.

Eu já estive lá e fiz algumas escutas interessantes que estou para postar em breve quando o tempo me permitir.

<Automatic translation from Portugese to English follows>

Hello friends,

Although I live in downtown Curitiba, a place with too much noise, I have not lost my hope that COPEL (Cia Energetica do Paraná) can solve once and for all with these dreadful noises that annoy my eavesdropping.

Proof of this was the last blackout in November/2009 of months during which I ran to my radio Tecsun PL-310 and turned in OM, has captured stations that could not before and during the short period of blackout no noise is presented Banda OM all clean, no noise. This shows that my apt, 3rd floor is a very good place to listeners since this problem was resolved.

I'm already in contact with COPEL and she returned saying that would solve the problem within 30 days, which in pessimism do not believe.

I want to take my information and link to the photos of my antennas Dxismo, the best place that I've got the beach was Itapoá, a superb location for this hobby, but unfortunately do not live there, only summer.

Opportunity to present my new home circular loop antenna of 1 meter in diameter made from the famous toy BAMBOLE. It took 1 year to cook this dish because it was a durable, flexible while at the same time that could be tied / attached to the hoop and he could follow the circumference of it. After much searching I managed to find a store leather / roof in downtown Curitiba expessura a cardboard from a 3 to 4 mm that had these features that I either needed to be able to cook this valuable and amazing antenna loop to OM. So here is my tip antenna loop for all.

She has a fantastic income, but due to ruideira this in my apt I am inclined to tapping into an inn at the foot of the hill Anhangava here in the city of Quatro Barras to some 50km from Curitiba. There the conditions are just fantastic.

I've been there and made some interesting that I'm listening to post soon when the weather will let me.

The link to the photos of the antennas is ...

www.4shared.com/dir/23830727/f1551468/minhas_antenas_para_Dxismo.html

and password to access the "antenas".

Steve, I agree English Please, but please trim posts, no need to have the whole original post.

This is in portuguese! You can use an online translator. He is just showing off his home brew antennas..... (I went to link, a picture hosting site). Not sure or forgot where he is from, must be Brazil? Portuguese. He could use the translator and post in English, than translate replies back. I think it's interesting. Internet is like SW radio, no telling who you will talk to. Lots of non english radio going on in the World, probably more than the USA, which is most religious broadcast. Europe and the undeveloped parts of the World still use Radio as a prime or important source of info and entertainment. Internet made the world smaller. OK philosophical rant switch off...

Cheers

Also, you might need to paste an "http://" at the beginning (before the www). Most web browsers don't care, but maybe some do.

That's probably why you didn't see it highlighted in blue. If so, highlight it, paste it into your web browser's URL bar, add the http:// and remove any spaces.

Some nice pictures. I liked seeing the use of a bamboo pole. I worked in Honduras as a teacher with the Peace Corps in 1982-84. One weekend I helped a civil engineer friend haul some pipe up the mountain for a water project he was building in a village. Somebody had left several long (8 meter or so) pieces of bamboo along the side of the road, so we picked one up on the way back. (I would have paid if someone had been around.) I wrapped wire around the top three meters and it made a very nice vertical antenna.

A group of operators from Associazione Radioamatoriale Sardinia
QRP Club will be active as IQ0QP/LH from Sant'Elia Lighthouse (Cagliari-Sardinia-Italy)
By Dec. 12, 18.00 to Dec. 13, 10.00 UTC).

.
A Low Power Beacon will be active
same time on 14.349.5 (CQ CQ de IQ0QP IQ0QP) .

.
Rigs that will be used: Yaesu FT817,
Elecraft KX1, (QRP), Rock Mite 40 (QRPp) ICOM IC706 and Kenwood TS140 (QRO).

.
Vertical quarter wave antennas 40
& 80 M .
Loop Antenna 20 M . EH Antenna @ 40 & 30 M .

.
We will operate on 20, 30, 40 and 80 m , SSB, CW and Dig. Modes
as follows

Bands/Frequencies/Modes

Band Freq. Mode

80 M 3560 +/- 10 kc

6933. Litz Wire - ferrite loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-11-30 01:18:19 UTC
From: sarmento2k
Topic: 6933 Message: 6933

Hi

This is my first post on this group, and I would like to show some pictures of two loop antennas I like most, mainly for MW dxing.

The first one, a square loop made with wood, which is either coupled passive, to portable receivers like Sony ICF-2001 or active, with a preamp buffering low impedance matching to 50 Ohms input of Icom R75.

http://www.sarmento.eng.br/LoopQuadroOM.htm

(it´s in Portuguese, but you may also see the calculations used on it)

The other one, is a loop stick ferrite antenna.

http://www.sarmento.eng.br/LoopFerriteRGP3.htm

Recently, I have found in my messy shack :-) some Litz wire, and I did a new coil based on it, and performance on MW is really a must comparing to the magnetic wire 23 AWG.

The Litz wire used is composed by 60 strands of 40 AWG, in theory, not the right one to MW, but it looks fine comparing to enameled wire 23 AWG.

Just to point that the day of the recently shaming blackout in Brazil, I listened to BSKSA Jedah, Saudi Arabia, 1512 kHz with excellent sound, using this antenna and a Sangean ATS909.

Post at : http://blog.sarmento.eng.br/2009/11/11/blackout-no-brasil-oportunidade-impar-para-a-radioescuta/

My question,is about Litz wire, does anyone have tested and compared the same kind of loop using different wires to measure its gain over "regular" one ?

Best Regards

I see the K parameters for the loops.
http://www.sarmento.eng.br/Figuras/geometria-k.gif

I suppose that does mean a circular loop is more efficient than a square loop??

I've always made circular loops, and yeah, should make some pictures;.
Here:

http://users.fulladsl.be/~spb13810/research/loop/

1 turn is for shortwave, about 6-7 turns for mediumwabve with this 83cm loop.
I never made a LW loop, but added some nF capacity and fell into the LW band with it...

Hi,

Jetpilot, the translator is just funny ;-)

very nice antennas --> antennas quite pleasant

who are the two beautiful woman? --> what is the woman two beautiful?

thanks for the post --> thanks to the connector

We have to use very simple (linear) phrasing ;-)

(what about reverting the translation back to original?)

Congratulations for the nice works presented by Sarmento

Have all a nice season there ;-)

6938. Stranded copper wire versus magnetic wire (enameled)

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-12-01 20:29:53 UTC
From: sarmento2k
Topic: 6938 Message: 6938

Hi,

Considering the windinds process for air coil loop, I have being using enameled copper wire.

I have seen lots of loop projects basically using standard stranded wire, instead of the magnetic wire used mainly in transformers.

My initial post is about litz wire in ferrite loops, but both subjects are interconnected.

I haven´t found yet a source proving in practical terms what´s the best material to achieve higher performance on MW (abstracting Litz wire for RF).

Does anyone has observed any practical differences in such approaches ?

Thks

The lower the resistance in the wire, the better. Stranding vs. unstranded only makes a difference if the resistance is lower. Litz wire should be excellent. A loop made of monster speaker wire is probably better for the same size. Copper plumbing pipe - the 1/4 inch type, would probably be even better. Low resistance = high Q = good loop. But bigger loops are always better, they can eclipse the choice of wire.

Two types of discussion I always bow out of: shielded and coax loops, and un-tuned loops.

But bigger loops are always better, they can eclipse the choice of wire.

Years ago, I found a huge spool of #16 stranded at a hamfest. Stranded trumps solid any day of the week - construction-wise. My MW 1m square loop of ten turns @ .5" spacing and tuned with a dual 365/409 pF variable cap and a single coupling turn 6" in from the tuned turns - and fed via zipcord to a 1:1 balun then the RG-58 to my receivers. I used it for my TTFD, too. Still a bunch left... great for construction - Litz wouls be better.

I am toying with the idea of recycling my 'Monster' speaker cables - twin large Litz-looking wires - as single/dual turn Tropical Band tuned loops - maybe 1 or 2 turns on a .7 - 1 meter form - tuned with a 3 gang variable cap. The problem is making a coax impedance tap on the turn(s) - how can I do that with the 'Monster' cable... isn't it a Litz-like wire?

John

PS The multi-turns of #16 stranded on the MW loop - and a newer smaller version - have wooden 'spreaders' weaved through them to take up the inevitable 'droop' stranded wire gets... a common malady with advancing age! The TTFD just worked better at lower frequencies...

Going from Portuguese to English is even funnier!
We have simple phrases to say it in English. ;-)

>> who are the two beautiful woman?
> what is the woman two beautiful?

Woman, Ladies, Girls, Females.... Chicas
In your post, you gave a link to pictures.
In one of those pictures were two woman.
The two woman were standing, arms out pointing.
They were pointing to a poster display on the wall, for an antenna.
You don't know what I am talking about?

Cheers

I suppose Litz wire could be called stranded wire ... but a very special kind. The 'skin effect' controls the RF conductivity of materials. Simply stranding un insulated strands of copper wire ... as is usual in normal stranded wire does not improve conductivity to the same degree as individually insulated strands ... as is the case with Litz type wire. it is possible to make your own Litz-like wire by stranding light gauge enameled wire. The enamel insulation is quite durable.

The main purpose of stranding un insulated copper is to provide strength and flexibility .... whereas the purpose of stranding insulated copper wire (as in Litz) is to improve the RF conductivity for a given wire guage. monster speaker wire may provide great flexibility and conductivity for DC & AF purposes ... but is nothing special when dealing with RF.

Hi Sarmento,

Generally speaking when one wants to construct a tuned loop - or any other tuned circuit - with highest possible Q one wants to use the best design and material that will present the least amount of resistance to RF currents in the inductor. The two factors that inhibit RF conductivity are 'skin effect' and 'proximity effect'.

Skin effect (RF conducts on the surface area) is overcome by using wire with the largest diameter possible .... or using multiple strands ... each insulated from the other. Ordinary stranded wire is not an improvement ... in fact it may be a poorer RF conductor than the equivalent diameter solid wire.

The other factor 'proximity effect' is the result of induced eddy current as one conductor is brought within the electrical field of another conductor that is carrying current. The resultant eddy currents inhibit RF current flow. Ideally it is a good idea to keep each turn out of the electrical field of the other.

1. strategy would be to use large conductors ... such as copper tubing in order to limit 'skin effect'... and to allow wide spacing between turns to limit the 'proximity' effect. This strategy is possible when space and

maneuverability is not an issue.

2. strategy is to use High Quality Litz wire .... which uses multiple insulated strands to limit 'skin effect' arranged in a special 'weave' (not all Litz wire are equal) to limit 'proximity effect'. This is best used effectively in projects with space limitations. By the way, special 'weaving' techniques can be used when actually winding your loop or coil. If you are going to construct a large loop with wide spacing then Litz wire will bring minimal returns. However if your inductor is small with tight winding on an iron core then Litz wire can be worth it's weight in gold .... good thing Litz wire is light hi hi.

The first strategy is limited to scenarios where there is no limit on size and weight. The second strategy is used where there are great limits on size and weight.

If you want to see dramatic examples of these two techniques do a search on crystal radio construction. Crystal Radio aficionados strive for tuned circuits with maximum Q .... essential since the rule is that all power comes from the received signal only .... no electronic amplification allowed !! I have seen crystal radio coils the size of 45 gallon drums !!

When trying to eke out the nth degree of efficiency the quality of the tuning capacitor can be a considerable factor ... but that is another story.

I have built any number of crystal radio receivers and found the same techniques for winding receiver coils are directly transferable to winding tuned loop antennas.

The only difference making a 20M magnetic transmitting loop with a gimmick capacitor is no different than using a regular capacitor, I have done both. Only use the gimmick capacitor if you intend to use low power (QRP).

Here is a link you will find interesting that uses both a gimmick capacitor and hardline for a compact loop:

http://www.antennex.com/hws/ws0902/hardline.html

I have built the above using 7/8" aluminum hardline and it does work with powers up to about 20watts.

All good stuff, except that I think proximity effect
involves the magnetic field of nearby conductors, not the
electric field.

Here is the most useful tutorial I have found on winding and
wiring eddy current losses, including proximity effect losses.
http://focus.ti.com/lit/ml/slup197/slup197.pdf

I'll put a link to this document on the link section for
this group.

Hi,

You are correct ... a slip of the grey matter ... the magnetic fields are
the fields of concern in this scenario.

Hi Alexis,

Are the loops you describe (the 4' and the ferrite rod version) tuned ? I am not familiar with the HDT-1 other than it is a HI-FI component generally installed in close proximity to your sound system. I believe it has a rear connection for an external AM antenna. As consequence you will have to provide some system of coupling from the tuned loop to the antenna input connection on the radio.

You have the problem that the signal from the 560khz station is not strong enough in relation the local noise. If I am correct the HDT-1 is not very portable. You mention shielding the loop. Shielding the loop (in my opinion) will not lower the noise .... let alone raise the 560 signal strength.

Increasing the listen ability of the setup will require the loop be tuneable, and be coupled to the radio by a lengthy feed line. The higher the loop Q ... the sharper it tunes and the better the quality the more it will increase the signal in relation to received background noise. The reason for the lengthy feed line is that it will allow you to locate the loop within the room to a spot with the least RF noise and best reception. If you were using a portable radio ... your best strategy would be to take both the radio and loop to a quiet location ... e.g. like out on the patio deck hi hi.

you need a quality tuned loop (shielding is irrelevant) .... it has to be designed with a coupling loop and feed line. You tune and locate the loop for best reception. You will be surprised how much difference there is in RF noise from one location a few feet from another. Of course orienting the loop for minimal noise will be part of the process.

Just a side light ... I have a component receiver which came with a small (8" 4 turn untuned loop) as the AM antenna. I made a small tuned loop (approx 1 ft square) tuned with a 365 pfd capacitor. I then used the small 4 turn loop as a coupling loop (just mounted it on the same frame as the tuned loop). The feed line from the coupling loop was simply a twisted pair of wire.... which i lengthened to about 10 ft. I would then locate the tuned loop for best reception. The untuned loop provided by the radio

manufacturer was only effective for strong local AM stations. the arrangement dramatically improved reception .... but still not as good as a portable out on the deck hihi.

Jim

Hi,
An interesting posting on loop antennas.
I came across some speaker wire advertised in the UK at £35 / metre ($63)
when I saw a sample it was like the wire you see on welding sets, 15mm dia jacket
and hundreds of fine strands, would this do a one turn loop ?????

Grundig YB-300PE AM/FM/SW Receiver + Tecsun AN-200 MW Loop Antenna Package.

Both the radio and loop antenna are LNIB and come with all original accessories, packaging and manuals. Items are in mint condition, both operationally and physically, and were well-cared for and in a smoke-free environment. Shipped double-boxed and well-packed.

$60 + actual shipping (your choice). Paypal preferred.

Honor and integrity mean everything to me- check out my feedback on ebay (ID= vectorczar).

Email me: KI4NEJ@...

Thanks,

Lee

How do you feed a loop balanced?

With what kind of a coaxial can it be possible, with two separate coaxial cables or with one with 2 inner wires? I happen to possess the latter type.

If I would use normal speaker-double-wire, would it not give me all kinds of electric disturbance?

With the special coaxial with 2 inner wires, would they not disturb each other?

Best Regards from Aimo

When the loop is fed balanced, the null is ALWAYS perpendicular to the

plane of the antenna.

If you feed it unbalanced, the null moves, or rather diminishes. As you

approach the first parallel resonance, the resonance the null will disappear

entirely. Above the first parallel resonance, the null will return to being

perpendicular to the plane of the antenna, but the phase will be reversed.

As you approach the first series resonance (between the first and second

parallel resonances), the pattern will rotate.

I learned this while doing extensive ELNEC/EZNEC simluations of

single-turn loops for my 2-part series on active loop antennas in the March

2007 issue of QEX. I did it to emphasize the point that loop antennas

should ALWAYS be fed balanced.

Chris,

I think Aimo may be asking about feeding with Twinaxial cable. I'm kind of curious about that myself. I have tons of twinax laying around from an as/400 de-installation.

You won't ba able to use Twinax by itself as you'll have a tremendous impedance mismatch. Somewhere, you will need a matching section (single frequency) and, if using coax, a BalUn transformer.

Hi Aimo,

by definition, a balanced antenna is symmetrical ... physically and electrically and does not require ground/earth as a counter-poise. The feed point is in the middle as far as the dipole/doublet is concerned and anywhere in the circumference of a loop. the radiation pattern of balanced antennas depends on the maintenance of electrical symmetry in addition to its mechanical symmetry. The electrical symmetry can be affected by objects (usually metal) in the vicinity of the antenna's magnetic field and/or the structure of the feed system.

Your question relates to the feed system of a balanced antenna and the maintenance of antenna balance. There are 2 connections at the feed point which should always be equal but opposite at any point in time - electrically speaking. A 2 wire feed line is ideal in this respect ... such as speaker cable, TV twinlead, twisted pair, etc.

You mention 'disturbance' .... I am not quite sure what you are referring to. If you mean that the feed line is picking up signals in addition to the antenna ... then you should not be concerned. A 2 wire symmetrical feed line such as 75 or 300 ohm twin lead if connected to a balanced antenna and a balanced input at the receiver will not add any signals picked up by the feed line to the signals picked up by the antenna. The reason is that the conductors pickup antenna currents as if they were 1 wire and the currents cancel at the antenna and at the receiver input ... leaving only the antenna currents fed to the line by the antenna.

As soon as you use coaxial cable you introduce a balance problem. The problem being that the advertised cable ratings are those between the center conductor and the inside of the shield. However, if precautions are

not taken to isolate the inside of the cable shield from the outside then antenna currents will flow on the outside of the feed line and mix with the currents from the antenna. The irony of this is that the coax feed line will pickup more 'disturbance' than a simple unshielded pair !!

The second major concern when designing an antenna feed line system is matching and feed line efficiency. That is getting as much of the antenna signal to the radio via the feed line/and or amplifier .... which is quite a different matter to the concern for balance.

Jim

Thanks, Chris!
I do not know the impedance of my Twinaxial cable.
What kind of a matching section would you suggest?

I have used Twinaxial as a loop on my inner wall, and it gives a rather good signal when an A.T.U is used between it and my Ten-Tec RX340.
I also use it between my 75 Ohm Loop and A:T.U. with much equal results.
Both systems give me very good signals with the same stations as my other antennas on the roof, an 8-wire, 3-wire, Broom Stick, DX 1 Prof. MK 2 and Wellbrook 100M!!!!!! All of the mentioned are downloaded with coaxial cables, either 50 Ohm or 75 Ohm.

What might be wrong here in Spain to me not being able to listen to real DX?
I mean the low powered broadcasting stations of the world, which are very well heard in Finland. I will not move to the cold northern countries any more! But I really would like to continue this best hobby of the world....

Best Regards from a frustrated Dxista.

Interesting - I found 3 different impedance references for twinas - 78, 95, 100 Ohms.

http://www.amphenolrf.com/products/twinax.asp?N=0&sid=4B258000A4B617F&

http://www.connectworld.net/tms/0-CAB-TWINAX-PL.html

Probably will have to research impedance by working off of cable part number before deciding on proper impedance transformation. Then again, if you are connecting the conductors in parallel (tying together at each end) or in series creating a continuous coil of 2 turns, you should not have to worry about characteristic impedance for connecting to a feedline to your radio. I would think that the capacitance between conductors in series would go more towards frequency resonance calculations.

I've ordered a couple of 13.5" 125u rods, and made a really nice tuned ferrite rod antenna for MW dxing. works very well. I used Litz wire to do the windings. Very sharp tuning, and when inductively coupled to the ferrite on several radios, truly enhances the signals. I'm thinking of doing up a nice LW antenna for NDB Dxing with my R75, using a coupling section to input into the high Z in the radio...

THese rods are fantastic.

I used a similar rod for my active ferrite rod antenna, using a somewhat novel approach to the remote tuning which provides a much higher signal voltage to the amplifier:

Hello!

What kind of variable capacitors do you want?
Let me know exactly, and I will try to contact Bebek for you.
Please, give a perfect list, so I will be able to ask Bebek,
if they still have those variable capacitors.

Another rather inexpencive source is in Lithuania:

Gintaras Sakenas, P.O.Box 1367, Vilnius, LT-2056, Lithuania

I have purchased many different parts from this Radio Amateur,
who is a very reliable and fast source, who packs the parts really well. His prices are very low...

Aimo

Arrow Antennas makes an ultra light weight 2 meter/440 MHz
portable Yagi with a handle for satellite work. It is
also great for direction finding. It breaks down and fits
in a carrying case. Highly recommended.

A great 440 antenna is 4 ele quad antenna on 440 using copper clad steel and a single spreader. Make them round and its pretty easy and small.

Good luck, Art.

Hello Frits,

The final phase of a search can be done with attenuators. Once your close, throw in 20 dB of attenuation, then 40, and so on. A 100 dB switched atenuator, and very good shielding between the attenuator and the radio, and of the radio itself (aluminum foil?) are required for transmitters that are more than about 1 watt.

One technique is to do the spiral search. Which was taught to me by a pilot. Proceed on a bearing from far out as best as you can tell directly towards the target. Stay on the same bearing without turning, until your antenna indicates a 90 degree variation from the original bearing. Then turn in that direction 90 degrees. Proceed on the new bearing again, until the antenna indicates 90 degree deviation from the bearing. Duplicate this over and over, with more and more attenuation, and even with a yagi you cannot help but walk right into the target.

The "spiral" search pattern is a good technique to keep in mind. It can be an effective tool in your bag-O-trick for RDFing.

While the importance of shielding everything behind the attenuator cannot be over emphasized for "close-in" work, a much better approach (and a another handy tool) is the use of an "Offset Attenuator." Arrow makes one that works well and there are simple kits for low cost. Do a Google Search for "Offset Attenuator" and you'll see how they work.

6975. 160 mtr loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2009-12-22 14:11:20 UTC
From: g8jvm
Topic: 6975 Message: 6975

Hi all

I'm primarily a VHF to microwave person, but the activity up there is awful now
I've been looking at 160 mtrs.
here's the question:-

If I used the vhf/shf antennas on the tower as a frame, the circumference after I've extender the boom s with insulating material will be about 21mtrs, sorta oval shape, I'd prefer not to capacitively shorten if possible. I can reduce the circumference by 1 mtr so that 8 turns would give a full wavelength, or use 4 turns and make it resonate on 80mtrs and use a switchable fixed capacitor to resonate it on 160 mtrs.
Although I can insulate the turns of the loop from the other antennas and the vhf/shf antennas wont see the loop as it will be far less than the width of the booms, does anyone know what effect having all that metal inside of a loop will have on it.
Anyone tried this approach ??

thanks

Richard G8JVM

Richard,

Take a look at Ben G0CWT's loop website. I use his designs exclusively for 160M to 40M with outstanding results.

http://g0cwt.co.uk/magloops/

Very simple to build and tune. I had the 80/160 version up and tuned in less than 2 hours.

Go back in time to the 40's and 50's. It was a coil of resistance wire, usually wound on a ceramic former about 3/4" diam and 10" long, which was the element for an electric room heater. With Brit 240 v a.c. across the ends it sucked around 4 Amps out of the wall socket. It was an inefficient and rather inductive dummy load which was capable of sending a few watts of top-band a good couple of miles, especially if used in upper storeys of buildings.
Sometimes our versions of "English" and terminologies will clash.
Sorry Briggs, Regards, Mike.

I have built a 1 metre square loop for the 550 to 1700 khz bnd and I am not sure on the size and placement of the pickup loop. My intention is to eventually put the loop in the attic and use RG58U to bring the signal to my radio (grungig S350). Have been experimenting with pickup loop but not sure I am doing it the best way. Results don't seem to be as good as I had hoped for. I am kind of new to this so my expertise is limited. Would appreciate any and all suggestions. Thanks in advance.

HI,

The 1 meter loop for MW broadcast reception works best when tuned ....
making a remote attic location a problem (remote tuning is possible of
course). The loop works best when inductively coupled to radios like the
S350 which uses a tuned ferrite loop front end. If you imagine the tuned
front end of the S350 to be the pickup loop you can see that the best
'placement' is not a fixed relationship .... the amount of coupling that
works best varies.

I find that a tuned loop with a coupling/pickup loop works best with radios
that are shielded and do not have a built in ferrite tuned front end/
antenna. they also have a balanced input. As a consequence coax feed line
is not the best solution unless used in conjunction with some kind of balun
arrangement. It is just as easy to use parallel feed line such as a
twisted pair, zip cord, or speaker cable. There is really no need for coax
if you couple the balanced pickup loop to balanced cable to a balanced
radio input.

I have an excellent AM radio in my HI-FI setup which has a balanced
input. I moved my box loop around the living room to the best (quietest)
location and run a feed line made of parallel speaker cable to the radio
(25 ft). I put the radio on the frequency of choice (digital tuning) and
just touch up the loop tuning. Great listening !!

Now if I were to put the loop in the attic I would have to devise some
means of remotely adjusting the loop tuning. there are only about 3 DX
stations I regularly listen to ... so I suppose the easiest method would be
to use 3 capacitors .... each tuned to the station of choice and switched
in with relays.

PS my pickup loop is adjustable .... it is about 8" in diameter and
consists of 4 turns of hook-up wire on a plastic loop. It's position can
be changed by slightly rotating it on its axis which changes in relation to
the loop axis (about 2' in diameter). Adjust the loop for the 'just right'

spot ... between amount of pickup and maximum loop Q. The 'just right' coupling is only critical with the weakest dx stations.

Jim

Hi. How would you tune it, have it fixed on one station or what! Mike {UK} mbe

Hello, good night and Merry Christmas to you and all your family. Well in the case of this receptor is not necessary that you do the "loop" procedure, simply bring the receiver antenna, below the wires and fine-tune your radio and antenna. Ready this is the best result, but if you prefer to connect the coaxial cable, make a loop of 50 cm in diameter and place the center of the antenna (the table) and connect a coaxial cable with good quality in your receiver, also is a good option, but rather only the approach to this case, as in the medium wave receiver has a ferrite antenna inside.
The cable for connecting the antenna to the radio, not necessarily a thick cable, you can even use a thinner cable and even a wireless connection to speakers, the result is satisfactory, what you can do is to use cable between the antenna and radio too large, it creates a signal and also changes the characteristics of the antenna, which can vary the frequency pre determined. I have a dish of medium wave and to use only the antenna by induction.
Good luck and I hope I have helped you, sorry for my English.

Respectfully
